**079344 RESISTIVELY INDUCED PLASMA DIFFUSION DUE TO THE TRIVIAL MARGINAL MODES OF IDEAL MHD.** The influence of nonlinearities and plasma resistivity on the so-called trivial marginal modes of ideal MHD is investigated. It turns out that to lowest significant order of a reductive perturbation analysis nonlinearities have no influence, while in toroidal confinement configurations resistivity induces a local plasma diffusion across the magnetic surfaces. This is demonstrated for tokamaks with zero poloidal current density. In addition, the appearance of singularities in the plasma motion parallel to the magnetic field lines suggests a profile condition at the edge of the plasma. Heat conduction would directly tend to keep these effects at lower level, while indirectly it creates a reinforcement mechanism through the coupling to usual cross diffusion. (Author abstract) 5 refs.

Dissociation

**079345 DETERMINATION OF THE DEGREE OF DISSOCIATION OF HYDROGEN PLASMAS.** The degree of dissociation of hydrogen plasma bounded by cylindrical metal discharge vessel walls is calculated. The problem is solved in the diffusion approximation neglecting loss of atoms in the volume. It is shown that under certain conditions the degree of dissociation is independent of the association coefficient for atoms at the walls. (Author abstract) 13 refs.

Electric Conductivity See Also ELECTRIC POWER GENERATION—Magnetohydrodynamic; ELECTRIC SWITCHES—Computer Simulation; ELECTRIC SWITCHES—Research.

**079346 ELECTRICAL CONDUCTIVITY OF COMPLETELY IONIZED NONIDEAL PLASMA.** Using the Kubo formula, the electrical conductivity of completely ionized plasma in the region  $\Gamma = e^2 / r_D T > 1$  ( $r_D$  is the Debye radius;  $T$  is the temperature) is calculated. First, the influence of flow effects is taken into account. The electron mobility for energies above the flow level is determined by methods of the theory of an effective medium, and depends on the characteristic scale of inhomogeneity of the potential and the velocity of electron motion in potential relief. The theoretical electrical-con-

ductivity values are compared with the experimental data and the results of other calculations. (Edited author abstract) 13 refs.

**079348 PLASMA RESISTIVITY AND FIELD PENETRATION IN JET.** The evolution of current and temperature profiles in JET has been analyzed using an advanced equilibrium analysis code and absolutely calibrated ECE measurements. It is found that during the discharge 'flat-top' the evolution of the current is well described by neoclassical resistivity. However, during the discharge rise phase, the current penetration can be more rapid. The MHD processes influencing the rapid penetration are discussed qualitatively by analyzing the trajectories of several discharges in the  $(q_0, q_a)$  plane. (Author abstract) 20 Refs.

## Electric Field Effects

**079349 OCCURRENCE OF ELECTROKINETIC INSTABILITY DURING DISCHARGE OF AN IONIZED JET.** A physical model of the occurrence in an electric field of ion-plasma oscillations in an ionized gas jet due to electrokinetic interaction is examined. The presence of such oscillations is confirmed experimentally by measuring the charge of the circuit, the capacitance of which is the conductive part of the jet of the gas plasma generator. The mechanism of occurrence of electrokinetic instability is examined for the case of a freely discharging jet in an approximation when the charged component does not have a substantial effect on the flow. 3 refs.

**079351 PARTICLE PATHS AND PHASE PLANE FOR TIME-DEPENDENT SIMILARITY SOLUTIONS OF THE ONE-DIMENSIONAL VLASOV-MAXWELL EQUATIONS.** Lie group point transformations applied to the one-dimensional Vlasov-Maxwell equations yield general similarity forms for the dependent and independent variables. One class of such solutions is seemingly like Bernstein-Greene-Kruskal solutions in allowing a relatively free choice of electric field, but with a more complex time dependence. The phase trajectories of the particles are found here for both temporally damped and (possibly unphysical) growing electric fields in this class by numerical integration in the

original and in transformed co-ordinates. The analysis, which includes an analytic consideration of phase-plane fixed (critical) points, shows the advantages of the new co-ordinates, and reveals qualitative features of the distribution function. (Author abstract) 21 refs.

## Electric Field Measurement

**079352 CONTACTLESS METHOD FOR STUDY OF RADIO-FREQUENCY PLASMA FIELDS.** A method is developed for study of localized microwave fields in plasma by means of a diagnostic electron beam. The fields are measured by analysis of the radio-frequency modulation of the electron beam by means of phase analyzer. The method permits measurement of rf electric fields with a characteristic field-localization dimension of  $\leq 1$  cm and a field strength of  $\geq 10$  v/cm in a band of  $\pm 20$  MHz relative to the reference signal. Measurements are performed in the 10-cm band. (Author abstract) 5 refs.

**079356 PROBLEMS OF PLASMA DYNAMICS OF JET DISPERSE SYSTEMS, JOINT PHYSICAL AND COMPUTATIONAL EXPERIMENT.** A survey of the status of research into high-temperature dust-laden jets of a complex gaseous composition and of the processes of interaction between molten particles and a base under the conditions characteristic of plasma coating deposition is presented. Results obtained at the Institute of Thermophysics of the Siberian branch of the Academy of Sciences of the USSR within the framework of development of a methodical approach are outlined. This approach makes it possible to tackle the research into the processes of impulse, heat and mass transfer in plasma jets of a complex chemical composition, both single-phase ones and those carrying inert impurity particles. The most important problems of research are formulated. (Translated author abstract) In Russian. 66 refs.

**079360 GAS DYNAMICS OF THE BOUNDARY LAYER OF A CAPILLARY DISCHARGE WITH A VOLATILE WALL.** Investigations of a capillary discharge with a volatile wall (CDVW) have established that as the length of the capillary increases, the pressure of the plasma in it increases linearly, if the other parameters remain constant. The purpose of the present investigation was to clarify the space-time characteristics of the plasma flow in a CDVW. This work was stimulated by the observation of an entire series of small deviations from constant values of the characteristics of the CDVW within the flat part of the current pulse. The geometric structure

of the boundary layer of a quasistationary capillary discharge with a volatile wall is studied as a function of its length. (Edited author abstract) 8 refs.

**079361 HEAT TRANSFER OF PARTICLES IN PLASMA FLOW.** Small spherical particles injected into a flowing high-temperature plasma stream attain an increase in heat energy by conduction and convective heat transfer. Because of the non-linear temperature dependence of the material functions and the transport properties of the plasma gas, the solution is usually obtained by an extensive numerical method. This paper describes a simple and fast polynomial series method to calculate the transient radial temperature distributions and the required melting time of single-phase particles as functions of the plasma temperature and velocity fields. (Author abstract) 14 refs.

Lee, H.E. (CSIRO Div of Applied Physics, Lindfield, Aust.). *J Phys D* v 21 n 1 Jan 14 1988 p 73-78.

**079362 FROZEN STATE OF IONISATION IN A CATHODIC PLASMA JET OF A VACUUM ARC.** The regions and conditions in which the Saha equation can be applied to the cathodic plasma of a vacuum arc are examined. Considering the relaxation times of ionization and recombination, it is found that the plasma is in a frozen state of ionization due to the rapid expansion for  $r \geq (10-100) \mu\text{m}$ , where  $r$  is the distance from the cathode spot. As a consequence, the electron density and all ion densities should be proportional to  $r^{-2}$ . The parameters of the frozen state accessible to experimental investigations ( $r > 100 \mu\text{m}$ ) result from the parameters of the strongly non-ideal plasma of the cathode spot. This opens a new approach to investigate strongly non-ideal plasmas by comparatively simple methods. (Author abstract) 11 refs.

**079364 PLASMA JET OPERATED BY SUBLIMATION GASES.** Evaluation of performance has been made empirically for an original type of plasma jet which is operated by using sublimation gases of solids. Both the production and the heating of the sublimation gases are conducted at the same time by arc discharges; hence the working gases can be generated on demand. The extinctions and ignitions are possible, repeatedly and instantaneously, with the application or interruption of arc discharges when appropriate solids are employed as its charge, and the sublimation rate of the charge can be controlled by the arc intensity. Measurements show that the efficiency of this plasma jet is in no way inferior to the ordinary gas plasma jet, and can be further improved by employing a composite type of charge solid or a consumption type of electrode in order that the evaporation gases may react and release high combustion energy. (Author abstract) 3 refs. In Japanese.

**079367 NEW STATIONARY VORTEX SOLUTIONS OF THE HASEGAWA-MIMA EQUATION.** Two different families of explicit stationary solutions of the Hasegawa-Mima equation are obtained. In the first case the well-known modon (dipole vortex) is used as the zeroth-order solution, and new solutions that are close to but distinctly different from it are found by perturbation analysis. In the second case the dispersive term of the equation is treated as a small parameter, and a radially symmetric solution (a monopole vortex) is used as the zeroth-order approximation. Both families of solutions are found to be infinite and to contain an arbitrary function. A recent general proof of the existence of infinitely many stationary solutions containing an arbitrary function is examined and found to be invalid. (Author abstract). 25 Refs.

## Heat Transfer

**079369 FOKKER-PLANCK CALCULATIONS ON HEAT FLOW IN PLASMAS.** This paper deals with the application of a Fokker-Planck code to the problem of heat conduction down steep thermal gradients. The results are compared with those obtained with other codes based on the Fokker-Planck equation in which various simplifying assumptions are made in the calculation of the Rosenbluth potentials. The particular problem considered is that of heat flow between spherical shells at different temperatures. The difference between the heat flows resulting from isotropic and anisotropic distributions is specially emphasized. The results show that, for calculating temperature, the usual Legendre polynomial expansion for the angular dependence of the distribution functions gives reasonable results even when it is limited to two terms. (Edited author abstract) 9 refs.

**079370 RADIATIVE HEAT TRANSFER FROM POTASSIUM SEEDED WATER GAS COMBUSTION PLASMA.** The radiative heat transfer calculation from a potassium seeded water gas combustion plasma has been made to estimate the heat losses through the walls of a MHD channel. The contributions of CO<sub>2</sub> and H<sub>2</sub>O to the heat flux are important, and more than half of it comes from bands lying up to 2.7  $\mu\text{m}$ . The heat flux from the potassium seed using various absorption cross-section data has been evaluated and compared. Potassium contributes about 25-30% of the total radiative heat flux. The radiative heat flux, both from combustion products and from seed increases about five times as the channel width increases from 8.4 mm to 2.0 m. 9 refs.

**079373 REQUIREMENTS FOR OHMIC IGNITION.** An analysis of ohmic ignition criteria is presented, giving the requirements on  $T$ ,  $n_r$ , and  $n/j$  in a form easily applicable to various confinement assumptions. For circular cross-section 'NeoAlcator' tokamaks with Spitzer resistivity, a value of  $B^2a$  approximately equal to  $250 \text{ T}^2 \text{ m}$  is required. The outstanding uncertainties in schemes to lower this value are how much increase in current density is achievable by plasma shaping and what the exact NeoAlcator coefficient is. (Author abstract) 9 refs.

Hutchinson, I.H. (MIT, Cambridge, MA, USA). *J Fusion Energy* v 6 n 3 Sep 1987 p 257-264.

**079374 INTERPRETATION OF ELECTRON CYCLOTRON HEATING RESULTS IN OVERDENSE PLASMA IN DOUBLET III.** The electron cyclotron heating (ECH) experiment on the Doublet III tokamak with inside oblique launch of the extraordinary mode has shown good heating even at very high densities, up to the operational density limit. According to ray tracing calculations for the high density discharges, the ECH waves are reflected at the periphery of the plasma around  $r/a$  approximately 0.9, and bulk plasma heating is not expected theoretically. But effective good heating has been observed in the increases of both the central electron temperature measured by Thompson scattering and the total energy measured magnetically. Furthermore, in the high density discharges, an extremely high density layer (marfe) exists in front of the antenna before the application of RF, and this layer persists for several milliseconds into the RF pulse. This paper describes a theoretical interpretation of this unexpected result of the good heating of an overdense plasma. The experimental results of the overdense plasma heating are reviewed, including information on the power deposition profiles, although the data are limited. Details of wave interaction with the high density plasma, starting with an intuitive expectation that deposition might take place in the plasma interior, are described. 18 refs.

**079375 H-MODE PHENOMENA DURING ICRF HEATING ON JFT-2M.** Significant improvement of energy confinement has been observed on JFT-2M during ICRF heating. This improvement is preceded by a sudden drop in the  $H_{92}/D_{92}$  emission and a successive increase in stored plasma energy, electron density and radiation loss. This is believed to be the same phenomenon as the H-mode transition observed in ASDEX, and in PDX divertor experiments with neutral beam injection. However, in JFT-2M, this transition is observed both in limiter discharges and in open divertor configurations. (Author abstract) 11 refs.

**079376 DIRECT RECOVERY OF ION BEAM ENERGY USING MAGNETIC ELECTRON SUPPRESSION - I. ANALYSIS OF ORNL ENERGY RECOVERY EXPERIMENTS.** The charge-exchange neutralization efficiency of positive ion-based neutral beams used in plasma heating applications decreases as the beam energy increases. Direct energy recovery from the remaining charged particles can be accomplished by electrostatically decelerating the positive ions; the space-charge neutralizing electrons are constrained from being accelerated by the application of a transverse magnetic field. A finite differ-

ence nonlinear sheath analysis is used to analyze the transverse magnetic field electron suppression experiments carried out at Oak Ridge National Laboratory in the early 1980s. A double plasma model, which assumes an equilibrium Boltzmann distribution of electrons at both the neutralizer potential and the ion collector potential, is used to study the experimental data obtained from operating 40 keV, 10 A ion beam energy recovery experiments. The effects of the magnetic field strength, ion 'boost' energy, and ion beam current density are examined in detail. (Author abstract) 43 refs.

**079377 CHARACTERISTICS OF ION BERNSTEIN WAVE HEATING ON THE JIPP T-IIU TOKAMAK.** Ion Bernstein Wave (IBW) heating has been examined on the JIPP T-IIU tokamak under two different conditions referred to as Mode-I and Mode-II. In the Mode-I regime, a wave is launched on an IBW branch between the third and fourth cyclotron harmonics of deuterium ions. In the Mode-II regime, a wave is launched on a branch between the second and third cyclotron harmonics. These two modes show quite different heating characteristics. The causes of this difference are analysed by using a simple model to determine the  $k_{\perp}$  spectrum of the excited wave and by applying a ray tracing code. In connection with the Mode-I experiment as discussed in a previous report (1985), two important new experimental results are obtained. It is shown that an IBW heats the core of the plasma rather than causing plasma-edge interaction, as anticipated. It is also shown that the energy tail of the hydrogen ions is higher than that of the deuterium ions, which indicates that the responsible heating mechanisms are different. (Author abstract) 18 refs.

Ogawa, Y. (Nagoya Univ, Nagoya, Jpn); Kawahata, K.; Ando, R.; Kako, E.; Watari, T.; Hirokura, S.; Kawasumi, Y.; Morita, S.; Sakai, K.; Sato, K.; Tanahashi, S.; Taniguchi, Y.; Toi, K. *Nucl Fusion* v 27 n 9 Sep 1987 p 1379-1388.

**079378 OBSERVATION OF HOT ELECTRONS PRODUCED BY SECOND HARMONIC ELECTRON CYCLOTRON HEATING IN THE AXISYMMETRIC TANDEM MIRROR GAMMA 10.** Microwave power,  $P_{ECH} \leq 140 \text{ kW}$ , has been injected at 28 GHz into the axisymmetric plug/barrier cell in the axisymmetrized tandem mirror GAMMA 10. As observed by soft X-ray measurements, the microwaves generate a hot (50-60 KeV) electron population, radially peaked on the magnetic axis, which results in the formation of a thermal barrier. The production mechanism of these hot electrons is found to be second harmonic electron cyclotron heating (ECH), corrected for the effects of the relativistic mass variation and the Doppler shift. This mechanism also explains the first experimental observation of a saturation of the single-component hot electron temperature  $T_{eh}$  as being caused by the finite width of the incident microwave lobe. (Edited author abstract) 37 refs.

**079379 ASYMPTOTIC APPROXIMATION FOR THE DISPERSION RELATION OF A HOT MAGNETIZED PLASMA.** An asymptotic expression for the dielectric tensor  $\epsilon$  of a hot magnetized plasma is obtained employing the steepest descents method, via the transformation of the components of  $\epsilon$  into their integral representation. The electrostatic Bernstein dispersion relation for oblique and perpendicular propagation is discussed under this treatment. It is shown that with this procedure the computation of the dispersion relation is up to 20 times faster when it is compared with the original expression, and the relative accuracy is usually as good as 0.1% for a typical case. (Author abstract) 22 refs.

**079380 MULTIPARABOLIC APPROXIMATION FOR RAY TRACING IN LINEAR PLASMA COLUMNS.** The equations for ray tracing in linear plasma columns with piecewise continuous quadratic electron density profiles are presented. Examples of calculations using these equations are given and compared with ray tracing in constant density shell plasmas. It is shown that significant savings in computing time can be achieved for long columns in which the rays undergo many radial oscillations. (Author abstract) 17 refs.

**079381 EFFECTIVE ION TAIL FORMATION BY BEAM AND ION CYCLOTRON HEATING.** Ion tail formation by neutral beam ( $D^0$ ) injection and second harmonic ion ( $D^+$ ) cyclotron heating in a 50:50 D-T plasma is investigated on the basis of a local Fokker-Planck calculation. The deformation of the deuteron velocity distribution function is examined analytically and numerically. The effectiveness of the tail formation is estimated from the enhancement of the D-T fusion reactivity,  $\langle \sigma v \rangle = \int d\mathbf{v} \rightarrow f(\mathbf{v} \rightarrow) G(\mathbf{v})$  ( $f$  is the deuteron distribution and  $G$  is the ' $\sigma v$ -function', averaged over the isotropic triton distribution). The profile of the integrand typically exhibits two humps in velocity space. This results in a large reactivity enhancement for high energy beam injection. For a radiofrequency (RF) induced tail, a 'wing' or smeared tail rather than a hump is formed. ICRF waves couple well with the beam induced tail ions and enhance the reactivity, especially when the beam is injected perpendicularly to the magnetic field. The efficient use of the power supplied by beam and RF waves to enhance the reactivity is also discussed. (Author abstract) 16 refs.

**079382 REQUIREMENTS ON HEATING OR CURRENT DRIVE FOR TEARING MODE STABILIZATION BY CURRENT PROFILE TAILORING.** A simple model is constructed which allows a systematic study of the effect of local heating or non-inductive current drive on tearing modes. The current profile changes due to the heating and current drive are calculated in steady state. An extensive study is made of the properties of the  $m=2$ ,  $n=1$  tearing mode within this model. It is shown that the effect of local heating on the  $m=2$ ,  $n=1$  mode stability is extremely sensitive to its localization. This sensitivity will, in practice, be prohibitive for mode stabilization by local heating. Non-inductive current drive is shown to be far more efficient in stabilizing than  $m=2$ ,  $n=1$  mode. The optimum effect of the non-inductively driven currents is obtained when it is positioned such that the current density gradient immediately inside the mode resonant surface is reduced. (Author abstract) 18 refs.

**079383 CORRELATION OF PELLET PENETRATION DEPTHS ON ASDEX FOR OHMIC AND AUXILIARY HEATED DISCHARGES.** Penetration depths for frozen  $D_2$  pellets into ASDEX ohmically and auxiliary heated discharges are reported for a wide range of plasma and pellet parameters. It is found that the data are well correlated by a single parameter  $Z = d_p^{5/3} v_p / n_{e0}^{1/3} T_{e0}^{5/3}$  (pellet diameter, pellet velocity, central electron density and temperature), which emerges from the neutral shielding model. The pellet depths, however, are systemat-

ically smaller than is expected from the model, implying a higher ablation rate in the outer plasma layers. (Author abstract) 9 refs.

**079384 ION CYCLOTRON HEATING IN TMX-U.** Ion cyclotron heating (ICH) is applied to TMX-U to improve the thermal barrier performance by reducing the passing ion collisionality. During its development, measurements of the antenna loading resistance,  $R_p$ , and the absorption efficiency,  $\eta$ , were compared with calculations with the antenna design code ANTENA over a wide range of densities and frequencies. Good agreement in  $R_p$  was obtained in the short wavelength slow wave regime but not for long wavelength fast waves because the experimental magnetic field gradients are not modelled in ANTENA. Similarly,  $\eta$  is much larger experimentally (40%) than in ANTENA (10%) due to the magnetic beach in TMX-U. In its application, ICH successfully decreased the passing ion collisionality tenfold but did not extend thermal barrier plugging to higher density, indicating that collisional barrier filling is not currently limiting TMX-U performance. (Author abstract) 23 refs.

**079385 IONIZATION, HEATING AND STABILIZATION BY CURRENTS ALONG A POLOIDAL MAGNETIC FIELD.** The ionization and heating effects of induced low frequency poloidal currents in the internal ring device FIV A have been studied. The start-up process is more efficient and works at lower filling pressures than without poloidal currents. The plasma temperature is increased due to ohmic heating. Rotating plasmas with a density of  $1.5 \times 10^{21} \text{ m}^{-3}$  were obtained for a filling pressure of 6 mTorr. Fluctuations are stabilized already at low power poloidal currents. The stabilizing effect seems to be related to the applied toroidal magnetic field rather than the induced poloidal current. At the lowest filling pressures (0.2 mTorr) a nonrotating plasma, sustained only by the poloidal current, with a density of  $1.5 \times 10^{20} \text{ m}^{-3}$  and a temperature of 7 eV was produced. At this low density, the plasma is permeable to neutral gas, as opposed to the impermeable plasmas in the earlier experiments with this device. (Author abstract) 10 refs.

**079386 TEST OF THE POWER-CARRYING CAPABILITY OF WATER-DIELECTRIC-LOADED ION CYCLOTRON HEATING WAVEGUIDE LAUNCHERS.** An external waveguide launcher is an alternative to an internal loop for launching high-power ion cyclotron radiation into the magnetically confined plasma of a fusion reactor. Water, filling the waveguide, can perform the dual function of dielectric medium and coolant, while remaining highly insensitive to the 14-MeV neutron flux from a fusion reactor. The results of tests on the power-handling capacity of a water-loaded-dielectric waveguide (WR1150) at frequencies of approximately 80 MHz are presented. A tunable radio-frequency cavity, which when filled with water resonates at 80 MHz, was used to achieve electromagnetic stress levels that approach that which ion cyclotron heating launchers would have to withstand in a fusion reactor. The tests show that the waterfilled WR1150 waveguide is capable of transmitting  $\geq 500 \text{ kW}$  at 80 MHz. (Edited author abstract) 8 refs.

**079387 SEMIANALYTICAL ANALYSIS OF ION VELOCITY DISTRIBUTIONS IN THE PRESENCE OF COMBINED NEUTRAL-BEAM AND ICRF-HEATING.** The energy clamping scheme with combined neutral-beam and ICRF-heating is considered. Assuming

the neutral-beam particles to be injected almost isotropically, an approximate equation is derived for the pitch angle averaged distribution function. Comparison between results obtained from this equation and those of a full 2D numerical calculation, shows good agreement for physically significant quantities, like total absorbed power, power transfer to background plasma particles and fusion reactivities. This indicates that the equation for the averaged distribution function should be useful in situations where time consuming 2D numerical calculations of the distribution function are impractical, e.g., in plasma transport codes. (Author abstract) 16 refs.

**079389 NEUTRAL PARTICLE EMISSION IN JET DURING RADIOFREQUENCY HEATING EXPERIMENTS.** The paper deals with the simulation of neutral particle spectra obtained in JET with an array of four passive neutral particle analysers during discharges with applied stationary or modulated radiofrequency power in the ion cyclotron range of frequencies for a deuterium plasma with hydrogen minority. The distribution function of the hydrogen ions has been computed using a one-dimensional Fokker-Planck equation describing wave-particle interaction by a quasi-linear diffusion term in velocity space. Both stationary and oscillating solutions of the Fokker-Planck equation have been worked out and the computed by hydrogen fluxes have been found to be in very good agreement with the measured ones. (Edited author abstract) 27 refs.

**079390 PARAMETRIC INSTABILITIES ASSOCIATED WITH INTENSE ELECTRON CYCLOTRON HEATING IN THE MTX TOKAMAK.** The paper presents a survey of possible parametric instabilities in the upcoming Microwave Tokamak Experiment (MTX) at the Lawrence Livermore National Laboratory in which an intense pulsed free-electron laser will be used to carry out electron cyclotron heating in the Alcator C tokamak. Potentially the most dangerous instability is stimulated Brillouin backscatter by electrostatic ion cyclotron modes or quasi-modes for ordinary-mode heating at the fundamental harmonic or extraordinary-mode heating at the second electron cyclotron harmonic. Large reflectances may occur for coherent microwave sources. In addition, extraordinary waves at the amplitudes considered here can be non-linearly absorbed by parametric decay processes at the resonance layers where the pump frequency equals the second electron cyclotron harmonic and where it equals twice the local upper hybrid frequency. **079392 TRANSITION FROM THE L-MODE TO THE H-MODE BY ELECTRON CYCLOTRON HEATING OF A TOKAMAK EDGE PLASMA.** Transitions of L-mode plasmas to the H-mode have been induced by an electron cyclotron heating (ECH) pulse. The transitions occur when ECH is applied to plasmas preheated either by a neutral beam or by waves in the ion cyclotron range of frequency with power levels well below their own threshold power for the H-mode transition. The position of the electron cyclotron resonance layer has been scanned and it has been shown that edge heating rather than central heating is effective in inducing the transition to the H-mode. (Author abstract) 20 refs.

**079393 ANALYSIS OF DIVERTOR PLASMA IN OHMICALLY AND NEUTRAL BEAM HEATED HYDROGEN DISCHARGES IN JT-60.** The characteristics of ohmically and high power neutral beam heated (PNBI approx. 20 MW) hydrogen divertor plasmas in JT-60 are analysed on the basis of a plasma fluid model. The calculated radiation loss of the divertor plasma and the density dependence of the neutral pressure in the divertor chamber  $P_{H_2}^{div} \propto n_e^{-2}$  are qualitatively in good agreement with the experimental results, the divertor radiation loss in ohmically heated discharges can be explained by hydrogen line radiation and impurity radiation. The higher neutral pressure in neutral beam heated discharges can be explained by the decrease of the global particle confinement time in comparison with that in ohmically heated discharges. (Author abstract) 26 refs.

**079394 ANALYSIS OF A MICROWAVE-HEATED PLANAR PROPAGATING HYDROGEN PLASMA.** The heating of a gas to high temperature by absorption of microwave radiation has been proposed as a potential electrothermal rocket propulsion system. One possible mode of microwave energy absorption is by means of a planar plasma region propagating toward the source of the microwave radiation. Such a planar propagating plasma can be spatially stabilized by a gas stream flowing in the same direction as the microwave with a velocity equal to the plasma propagation velocity. A one-dimensional analysis of the microwave-heated planar propagating plasma for hydrogen gas was developed to predict maximum gas temperatures and propagation velocities. The governing electromagnetic and energy equations were numerically integrated with temperature-dependent thermodynamic properties of equilibrium hydrogen. The propagation velocity eigenvalue was solved by means of an iterative technique. (Edited author abstract) 19 refs.

**079396 FORMATION OF STABLE, HIGH-BETA, RELATIVISTIC-ELECTRON PLASMAS USING ELECTRON CYCLOTRON HEATING.** A one-dimensional, steady-state, relativistic Fokker-Planck model of electron cyclotron heating (ECH) is used to analyze the heating kinetics underlying the formation of the two-component hot-electron plasmas characteristic of ECH in magnetic mirror configurations. The model is first applied to the well diagnosed plasmas obtained in SM-1 and is then used to simulate the effective generation of relativistic electrons by upper off-resonant heating (UORH), as demonstrated empirically in ELMO. The characteristics of unstable whistler modes and cyclotron maser modes are then determined for two-component hot-electron plasmas sustained by UORH. Cyclotron maser modes are shown to be strongly suppressed by the colder background electron species, while the growth rates of whistler modes are reduced by relativistic effects to levels that may render them unobservable, provided the hot-electron pressure anisotropy is below an energy dependent threshold. **079397 NEUTRAL IRON GENERATION WITH SAWTOOTH OSCILLATION IN TEXTOR ICRF HEATED PLASMAS.** The emission of neutral iron atoms from a metal target in the shadow of the limiter was investigated during ICRF heating of the TEXTOR plasma, using laser induced fluorescence. By collecting the data over many similar sawtooth periods, the sawtooth oscillation of the neutral iron density was found for the first time. The sawtooth oscillation of the neutral iron density occurring during additional heating was in reverse phase to the neutral oxygen flux from the main limiter, but in phase with the central electron temperature. On the other hand, another case which was in contrast to the above case was found. The incident ion on the metal surface was studied. (Author abstract) 23 refs.

**079398 EXPERIMENTAL STUDY OF EFFECTIVE PARTICLE HEATING BY A THERMAL PLASMA FLOW CONFINED IN A POROUS CERAMIC TUBE.** The heating of a single alumina particle (1 mm diameter) was experimentally investigated using a thermal argon plasma flow confined in a tube. Two kinds of tube were used; a porous ceramic tube (PCT) with a transpiration gas and a water-cooled copper tube (WCT). The temperature and velocity of the particle heated in a thermal plasma flow were measured at the exit of the tube by the calorimetric and optical method, respectively. The plasma temperature and velocity at the exit of the tube were also measured. The heating rate of a particle was estimated from these experimental results. According to the results, the heating rate of a particle is higher for PCT with a small flow rate of transpiration gas than for WCT. Therefore, PCT is effective for the particle heating. (Author abstract) 10 refs.

**079400 EFFECT OF ION LOSS ON ICRF HEATING.** The effect of spatial loss on ICRF ion cyclotron range of frequency wave heating is studied. A simple model for the energy-dependent loss term is adopted in the Fokker-Planck equation. The case of the minority ion heating by fundamental cyclotron resonance is analysed. It is found that the high energy particle loss imposes a limit on the heating power density, above which an increase in the heating power does not raise the energy transfer to the bulk particles, i.e. the heating efficiency deteriorates. This power limit is serious for losses with strong energy dependence such as ripple diffusion. Small spatial loss can annihilate the increment of the fusion reaction by tail generation. (Author abstract) 27 refs.

**079401 D III-D DIVERTOR TARGET HEAT FLUX MEASUREMENTS DURING OHMIC AND NEUTRAL BEAM HEATING.** Time resolved power deposition profiles on the D III-D divertor target plates have been measured for Ohmic and neutral beam injection heated plasma using fast response infrared thermography ( $\pi \leq 150 \mu\text{s}$ ). Giant Edge Localized Modes have been observed which punctuate quiescent periods of good H-mode confinement and deposit more than 5% of the stored energy of the core plasma on the divertor armour tiles on millisecond timescales. The heat pulse associated with these events arrives approximately 0.5 ms earlier on the outer leg of the divertor relative to the inner leg. The measured power deposition profiles are displaced relative to the separatrix intercepts on the target plates and the peak fluxes are a function of core plasma density. (Author abstract) 11 refs.

**079402 SAWTEETH, TRANSPORT AND ELECTRON CYCLOTRON HEATING IN T-10.** The paper presents transport code simulations of sawteeth discharges in T-10. Two models were employed to describe the sawtooth oscillations. In the first (reconnection) model the sawtooth collapse is caused by complete reconnection. In the second (turbulent) model the collapse is ascribed to increased radial transport caused by the generation of turbulence at some critical size of the  $m = 1$ ,  $n = 1$  magnetic island. For one particular discharge the predictions of the two models for the temperature, density and current profiles as well as the evolution of the heat pulse generated by the sawtooth collapse were analysed in detail and compared with the experiment. Also the influence of both central and off-axis heating by electron cyclotron waves on the sawtooth dynamics as given by the two models was investigated and compared with the experiment. In all respects good agreement with the experiment was obtained with the turbulent model. In contrast, it was not possible to obtain satisfactory simulations with the reconnection model. (Edited author abstract) 24 refs.

**079403 ICRF HEATING EXPERIMENT USING A PHASED ANTENNA ARRAY.** The paper discusses the results of a heating experiment in the ion cyclotron range of frequencies (ICRF) conducted on the JIPP T-IIU device with a five-element antenna array. This antenna

system provides precisely shaped  $k_{\parallel}$  spectra which vary according to the relative phasing angle of the neighbouring antennas,  $\Delta\pi$ . In the experiment,  $\Delta$  is scanned in a close pitch and it is found that the electron heating efficiency is drastically improved with  $\Delta = \pi$  and the lowest efficiency is obtained with  $\Delta = 0$ . This observation is analysed by calculating the  $k_{\parallel}$  spectra and then the power deposition profiles using a ray tracing code. It is also found that the effect of the phasing on the impurity problem is unexpectedly small. The reasons for the discrepancies between these data and theoretical expectations are also discussed. (Author abstract) 15 refs.

**079404 NUMERICAL MODELLING OF LOWER HYBRID RF HEATING AND CURRENT DRIVE EXPERIMENTS IN THE ALCATOR C TOKAMAK.** A simulation model is described for lower hybrid (LH) current drive, rampup, heating, and sawtooth stabilization. The model incorporates a one-dimensional radial transport code, parallel velocity Fokker-Planck calculation, and a toroidal ray tracing code. For steady LH current drive it is found that the RF current generation is accurately predicted by a fast electron confinement time of the form  $\tau_1 = \tau_0 (\pm) \gamma^3$ , with  $\tau_0 (\pm) = 3$  ms in the density range  $3 \times 10^{19} \text{ m}^{-3} \leq n_e \leq 7 \times 10^{19} \text{ m}^{-3}$  (where  $\pm$  distinguishes electrons moving parallel (antiparallel) to the current drive direction). Also in this range, the theoretically predicted wave absorption and experimentally measured electron temperatures and stored energy were found to be consistent with an electron thermal diffusivity whose magnitude is independent of  $n_e$ . (Edited author abstract) 41 refs.

**079405 ANOMALOUS TRANSPORT AND ANOMALOUS HEATING DUE TO LOWER-HYBRID WAVE FIELDS.** The microscopic and macroscopic behaviours of a linear reflex discharge in the presence of low-frequency turbulence are investigated under the action of moderate lower-hybrid wave power. The frequency and wavenumber spectra of both the low-frequency fluctuations and the high-frequency waves are measured using a correlation-analysis technique with two probes. The wavenumbers observed in the lower-hybrid resonance region outside the antenna are - in contrast with expectation - not larger than in the plasma edge region. From the electric-field energy-density spectra and from measurements of the density and the temperatures, a detailed energy balance can be performed. The calculated heating rates are anomalously large for both the electrons and the ions. The absorption processes, relevant for the present experiment, are discussed. (Edited author abstract) 37 refs.

**079406 HEAT PULSE PROPAGATION: DIFFUSIVE MODELS CHECKED AGAINST FULL TRANSPORT CALCULATIONS.** The problem of deducing  $\chi_e$  from heat pulse propagation measurements is addressed. An extended diffusive model is described, which takes into account perturbed sources and sinks.  $\chi_e$  is expressed as a function of two observables, the heat pulse velocity  $v_{HP}$  and the radial damping rate  $\alpha$ . A simple expression is derived in the typical heat pulse measuring region, i.e. 0.1 to 0.2 a outside of the sawtooth mixing radius:  $\chi_e = 4.3 \cdot v_{HP} / \alpha$ . Here,  $v_{HP}$  and  $\alpha$  are defined for cylindrical geometry, hence corrected for Shafranov shift and possible elongation of the plasma. This expression is checked against full transport simulations and found to be accurate. It is also shown that the

thus inferred  $\chi_e$  is a local value, not affected by the  $\chi_e$  profile outside the measuring region. (Author abstract) 12 Refs.

Lopes Cardozo, N.J. (JET Joint Undertaking, Abingdon, Engl); Tubbing, B.J.D.; Tibone, F.; Taroni, A. *Nucl Fusion* v 28 n 7 Jul 1988 p 1173-1181.

**079407 TMX-U THERMAL-BARRIER EXPERIMENTS.** Thermal-barrier experiments in the Tandem Mirror Experiment Upgrade (TMX-U) are reported, along with progress made at the Lawrence Livermore National Laboratory in plasma confinement and central-cell heating. Thermal barriers in TMX-U improved axial confinement by two orders of magnitude over a limited range of densities, compared with confinement in single-cell mirrors at the same ion temperature. It is shown that central-cell radial nonambipolar confinement scales as neoclassical theory and can be eliminated by floating the end walls. Radial ambipolar losses can also be measured and reduced. The electron energy balance is improved in tandem mirrors to near classical, resulting in  $T_e$  up to 0.28 keV. Electron cyclotron heating (ECH) efficiencies up to 42%, with low levels of electron microinstability, were achieved when hot electrons in the thermal barrier were heated to average betas as large as 15%. The hot-electron distribution was measured from X-rays and is modeled by a Fokker-Planck code that includes heating from cavity radio-frequency (RF) fields. Neutral-beam injection in the central cell created average ion betas up to 5% with radial profiles of hot ions that are modeled accurately by a radial Fokker-Planck code. Gas fueling between two fundamental ion cyclotron heating (ICH) resonances resulted in symmetrical heating of passing ions toward both ends. 30 refs.

**079408 ONE-DIMENSIONAL MODELING OF TRANSPORT IN SMALL STELLARATORS.** An existing stellarator reactor transport code was modified to model small stellarator experiments. Changes were made in the treatment of neutrals, the atomic physics process, and the transport models. The authors investigated the extent to which the hollow density profiles experimentally detected during electron cyclotron resonance heating (ECRH) experiments in the interchangeable module stellarator (IMS), a small modular stellarator, can be modeled. In this they were guided by the experimental observation of large variations in potential around the magnetic surfaces, which can give rise to radially directed  $E \times B$  convective flow. A diffusion model based on small-scale convective cell structures cannot simulate the experimental profiles. Including a purely convective term in the particle balance equation allows for a much more accurate modeling of the profiles. A comparison between numerical and experimental results is presented. 28 refs.

## Imaging Techniques

**079409 X-RAY TOMOGRAPHY ON JET.** Measurements of soft X-ray emission from the JET plasma have been analyzed with tomographic reconstruction methods. Because there are two detector arrays, two-dimensional images of X-ray emissivity are obtained without having to resort to rotation models. Several algorithms are employed in order to get as much detail as possible in the images while keeping any guiding assumptions to a minimum. The data analyzed so far have been used principally to study MHD instabilities, and illustrative examples of the sawtooth crash and of disruptions are described. (Author abstract) 28 refs.

**079410 IMAGING OF LASER-PRODUCED PLASMAS AT 44 Å USING A MULTILAYER MIRROR.** Images of imploding laser-fusion targets have been obtained using a spherical multilayer mirror. The mirror was coated to reflect Si XII 44.1 Ångström radiation and produced images of the coronal plasma regions of the glass microballoon and stalk. Clearly visible in the images are emission features as small as 40  $\mu$ m. (Author abstract) 21 refs.

**079411 APPROACH WITH THE AKAIKE INFORMATION CRITERION TO THE RADIATION DISTRIBUTION RECONSTRUCTION OF TOROIDAL PLASMA.** The Akaike information criterion (AIC) is used to optimize a spline function model for reconstructing the image of a toroidal plasma. The criterion is used to find the optimum number of B splines and to evaluate the effect of adjusting their positions. The behavior of the estimator is examined by numerical simulation and by analyzing an X-ray pinhole image of tokamak plasma. The results suggest the utility of the AIC in least-squares model-fitting approaches. 14 refs.

**Impurities** See Also NUCLEAR ENERGY—Fusion Reactions; TOKAMAK DEVICES.

**079412 RUNAWAY ELECTRONS DURING TOKAMAK STARTUP.** Runaway electrons significantly affect the plasma and impurity evolution during tokamak startup. During its rise, a runaway pulse stores magnetic flux inductively; this is then released during the decay phase of the runaway pulse. This process affects formation plasma, current initiation and current buildup. Because of their relativistic velocities the runaway electrons have higher ionization and excitation rates than the plasma electrons. This leads to a significant modification of the impurity behavior and consequently the plasma evolution. (Edited author abstract) 20 refs.

## Ion Sources

**079413 SURFACE-PLASMA SOURCE OF NEGATIVE HYDROGEN IONS.** The characteristics of a surface-plasma source with a gas-discharge cell with half-planotron geometry are studied. The beam of  $H^-$  ions has an intensity of up to 0.2 A, the normalized brightness is up to  $10^8$  A/cm<sup>2</sup>·rad<sup>2</sup>, the pulse duration is 200  $\mu$ sec, and the repetition frequency is up to 50 Hz. The source is a highly efficient generator of  $H^-$  ions and has a simple design. (Author abstract) 12 refs.

**079414 CALCULATION OF VALUES OF INTERACTION TERMS OF ELECTRON WITH ELECTRONS AND HEAVY PARTICLES FOR PARTIALLY IONIZED PLASMA.** To calculate the electron transport coefficients of partially ionized plasma the values of interaction terms of electron with electrons and heavy particles are necessary. In this paper these values  $H_{r,s}$  for r and s from the set (1, 2, ..., 16) are evaluated. (Author abstract) 2 refs.

Sado, Jerzy. *Bull Pol Acad Sci Tech Sci* v 35 n 9-10 1987 p 577-589.

**079415 IONIZATION EFFICIENCY IN A NEON, MEDIUM PRESSURE STATIONARY PLASMA.** The paper presents the quantitative results obtained for the ionization efficiency in the case of a neon, medium pressure stationary plasma within a pressure range of 2 Torr to 32 Torr and for discharge current levels from 80 mA to 400 mA. The ionization efficiency for this type of plasma is quite high, from about fifty percent to about seventy five percent. It is concluded that a neon, medium pressure stationary plasma is not worth being used as an optical radiation source. (Author abstract) 2 refs.

Toader, Emil I. (Univ of Bucharest, Rom). *Rev Roum Phys* v 32 n 7 1987 p 765-768.

**079416 THERMODYNAMIC DERIVATION OF SAHA'S EQUATION FOR A MULTI-TEMPERATURE PLASMA.** The ionization equilibrium between the constituents of a multi-temperature plasma is investigated within the thermodynamics of fluid mixtures. As a result, a law of mass action is derived that, in the approximation of ideal gases for the constituents, leads to a direct generalization of Saha's equation. The main properties of this generalization are discussed, and contrasted with those of other equations which have appeared in the literature. (Author abstract) 15 refs.

**079418 FAST-ION SPECTRUM EMITTED FROM LASER PLASMAS.** Broad- and narrow-band Nd glass lasers have been used to irradiate CD<sub>2</sub>, Al and Ta plasma targets at 0.3 - 2 × 10<sup>14</sup> W/cm<sup>2</sup>. Temporally-resolved fast-ion signals have been diagnosed by the Faraday charge collector oriented at 39° to the laser axis. There are two peaks demonstrating the motion of C and D ions in fast-ion spectra for the CD<sub>2</sub> target. For the Al target only one peak was observed, and for the Ta target the signal was very weak. High-translation energy of electrons and ions was obtained with the aid of laser field accelerations. Then the translation energy was converted into thermal energy by electron-electron or electron-ion collisions, and finally electrons and ions were heated to a high temperature. The translational energy and the temperature were calculated are consistent with those of the experiment. The dependence of the electron and ion temperature on the laser frequency bandwidth is quantitatively described. (Edited author abstract) 8 refs.

**079419 POLARIZATION DEPENDENT ENERGY TRANSFER IN LASER PRODUCED PLASMA EXPERIMENTS.** Polarization dependent light absorption in laser produced plasmas of small focal diameter (28  $\mu\text{m}$  full  $1/e^2$  width) has been investigated simultaneously in five different channels of observation: specular reflection of the laser light, second harmonic ( $2\omega$ ) generation, charge and velocity distribution of the emitted ions and ablation pressure to the target. The experiments have been performed using a Nd-YAG mode locking pulse ( $\lambda=1.06 \mu\text{m}$ ,  $\lambda=45 \text{ ps}$ ) which has been focused onto plane, thick plexiglass ( $\text{C}_6\text{H}_8\text{O}_2$ )<sub>n</sub> disks to intensities up to  $10^{14} \text{ W/cm}^2$ . As a result of the small focal spot size, a very small density scale length of  $0.6 \mu\text{m}$  is derived from the resonance curves, consistently, for all channels of diagnostics. (Author abstract) Refs.

**079421 ELECTRON THERMAL TRANSPORT IN LASER-TARGET PLASMAS ON THE BASIS OF GRAD'S 13-MOMENT TRANSPORT EQUATIONS.** Grad's 13-moment theory is used to model thermal transport in laser-produced plasmas where conditions are such that one may not assume that the plasma is collision-dominated. The equations are presented for a multi-fluid model in slab geometry and are solved numerically for various cases. Comparisons are made with classical theory and with simulations of collisionless plasmas. Results show that, although there are differences between 13-moment and classical predictions, the two theories agree on the general behaviour of the plasma. In particular, 13-moment theory fails to explain the heat-flux inhibition implied by some experimental observations. The theory has also been applied to model thermal transport in plasmas with a population of suprathermal electrons. (Author abstract) 18 refs.

**079422 EVIDENCE, FROM SPACE RESOLVED SPECTRA, OF  $2\omega_0$  HARMONIC GENERATION IN LASER IRRADIATED PLASMA FILAMENTS.** Space resolved spectra with both high spectral resolution ( $\approx 0.2 \text{ \AA}$ ) and spatial resolution ( $\approx 2 \mu\text{m}$ ) of the second harmonic emission scattered at  $90^\circ$  to the laser axis were observed when both narrow band and broad band laser beams were used in an Al planar target experiment. Analyzing many experimental phenomena, we have proved that the second harmonic emission observed at  $90^\circ$  to the laser axis is initiated by laser-plasma-filament interaction and not by planar-wave-plasma interaction. The experiments are, on the whole, in agreement with our theory. (Author abstract) 20 refs.

**079423 MODELS OF LASER-PLASMA ABLATION. PART 3. STEADY-STATE THEORY: DEFLAGRATION FLOW.** The theory of plasma ablation by laser irradiation from cylindrical and spherical solid targets is considered when thermal conduction is dominant and absorption is local at the critical density. Analytic solutions for both inhibited and uninhibited heat

fluxes are developed, but only investigated in detail when flux limiting does not introduce a step discontinuity. In most cases it is found that only a restricted region of flow is steady, and must be terminated by a rarefaction wave. The transition from quasi-planar to strongly divergent flow is shown to depend on a characteristic parameter, which represents the ratio of the thermal conduction length to the target radius. (Author abstract) 22 refs.

Pert, G.J. (Univ of Hull, Hull, Engl). *J Plasma Phys* v 39 pt 2 Apr 1988 p 241-276.

**079424 GENERATION OF  $\text{H}^-$  IONS IN A DIODE WITH MAGNETIC INSULATION WITH LASER PULSE INITIATION OF DIELECTRIC ARCING.** This work proposes a new system for generating pulsed kiloampere currents of negative ions in a diode with magnetic insulation with laser radiation initiation of surface arcing of a dielectric. The acquired results showed the effectiveness of the proposed method and its suitability for creating ion cannons. (Author abstract) 6 refs.

**079425 ENHANCEMENT OF ULTRAVIOLET LASER PLASMA EMISSION PRODUCED IN A STRONG STATIC ELECTRIC FIELD.** Enhancement of the ultraviolet (UV) radiation (200-350 nm) emitted from a laser produced plasma created on a gold target surface in the pressure of high negative static field by an order of magnitude was observed. The enhancement ratios for various spectral lines of gold atoms and gold ions, under a variety of voltage and laser pulse energy combinations were examined. A KrF excimer laser emitting at 248 nm was employed for generating the plasma. Electric field induced recombination processes are posited as a mechanism for the UV radiation enhancement. 20 refs.

**079426 A NEW TECHNIQUE FOR ESTIMATING THE DENSITY SCALE-LENGTH OF LASER PRODUCED PLASMAS.** The variation of frequency shift or stimulated Raman sidescattered radiation has been calculated theoretically as a function of the laser intensity, the density scale-length and the plasma electron temperature for a  $1.06 \mu\text{m}$  laser-produced plasma. Although this variation depends on all three parameters, the dependence is very strong on the density scale-length in the domain of  $1$  to  $100 \mu\text{m}$ . On the basis of this strong dependence, a new technique for estimating the density scale-length is proposed. (Author abstract). 18 Refs.

**079427 INFLUENCE OF THE BACKGROUND GAS PRESSURE ON THE ION MEASUREMENTS IN EXPANDING LASER-PRODUCED PLASMA.** Measurement of properties of ion emission from plasma generated by high power laser pulses is an important source of information about parameters of such plasma. The measurement of the number of emitted ions, their energy and ionization charge numbers to conclude about the plasma electron temperature, ionization-recombination processes and also anomalous processes occurring in laser plasma. An investigation was made of the influence of background gas pressure on ion emission properties in the case of comparable masses of the target and background gas atoms and the preliminary analysis of interaction processes. The obtained results show that the accuracy of the estimated plasma parameters is strongly affected by the background gas pressure higher than  $10^{-5} \text{ Torr}$ . 14 Refs.

**079428 RELATIVE STRENGTH OF SECOND HARMONIC AND  $3/2$  OMEGA EMISSIONS FROM LONG-SCALE-LENGTH LASER PRODUCED**

**PLASMAS.** Experiments were conducted on the planar slab targets of carbon, aluminum, and copper using a  $1.0641\text{-}\mu\text{m}$  laser at laser intensities varying from  $2 \times 10^{12}$  to  $1 \times 10^{14} \text{ W/cm}^2$ . The laser had a fluorescent linewidth of  $4.5 \text{ \AA}$ . Spectral profiles of parametrically modulated second-harmonic as well as  $3/2\omega_0$  emissions have been measured for the long-scale-length plasmas so generated. Relative strengths of these emissions with respect to peak signal intensity and spectral energy content as a function of laser intensity are graphically reported. Results are discussed on the basis of two plasmon and parametric decay instabilities. 33 refs.

**079430 STUDIES OF LARGE, NON-CIRCULAR, REVERSED FIELD PINCH DISCHARGES.** Reversed field pinch (RFP) discharges have been produced in a large aluminum vacuum vessel with indented sides. The discharges are self-reversed and ramped up to a current of  $300 \text{ kA}$  over a time of  $10 \text{ ms}$ . Reversal is sustained for  $> 10$  resistive diffusion times, despite the presence of large magnetic fluctuations. The influence of the bad poloidal magnetic curvature on RFP stability is examined by measurement of magnetic fluctuations near the plasma edge in the separate bad and good curvature regions of the non-circular plasma for RFP and non-reversed discharges with an edge safety factor,  $q_a$ , of  $0.4$  and  $1.4$ . For  $q_a$  approximately  $1.4$  discharges, the poloidal field curvature is small. The large device size permits RFP startup at a low toroidal loop voltage ( $< 200 \text{ V}$ ), which is applied to a gap exposed to plasma, but successfully protected against arcing (up to  $300 \text{ V}$ ). RFP plasmas have also been obtained with a toroidal limiter. (Edited author abstract) 14 refs.

**079431 CURRENT LIMITATION AND FORMATION OF PLASMA DOUBLE LAYERS IN A NON-UNIFORM MAGNETIC FIELD.** Formation of strong double layers has been observed experimentally in a magnetized plasma column maintained by a plasma source. The magnetic field is approximately axially homogeneous except in a region at the anode where the electric current flows into a converging magnetic field. For field strengths larger than about  $200 \text{ G}$  the double layer has a stationary position only in the region of non-uniform magnetic field or at the aperture separating the source and the plasma column. It is characterized by a negative differential resistance in the current-voltage characteristic of the device. Electron reflection by the resulting potential barrier is found to explain the essential features of the current-voltage characteristics observed, but further in-

vestigations of waves and fluctuations are required to clarify the current transport. (Edited author abstract) 20 refs.

Plamondon, R. (Univ de Montreal, Montreal, Que, Can); Teichmann, J.; Torven, S. *J Phys D* v 21 n 2 Feb 14 1988 p 286-292.

**079432 SLOW FORMATION OF FIELD REVERSED CONFIGURATIONS BY COLLIDING HIGH BETA COUNTER FLOWS.** To produce a field reversed configuration (FRC) without using the very high voltage techniques required in a conventional theta pinch, the author has studied the steady head-on collision of counter plasma streams, flowing along the magnetic field, as ejected from two identical co-axial plasma sources mounted at each end of the apparatus. The study was motivated by the fact that such a flow can be regarded as a steady state theta pinch. Ideal Poisson and shock adiabatic flow models were used to analyse the steady colliding process. It was demonstrated that an FRC involving a large number of particles can only be produced by the weak shock mode, which is achieved when energetic plasma flow is decelerated and heated up exclusively through the Poisson adiabatic process before the streams collide. (Author abstract) 19 refs.

Hirano, K. (Nagoya Univ, Nagoya, Jpn). *Nucl Fusion* v 28 n 2 Feb 1988 p 207-216.

**079433 EXPERIMENTAL INVESTIGATION OF DIFFERENT CONFIGURATIONS IN A FLEXIBLE HELIAC.** The effect of varying the magnetic field configuration by adding an  $n=1$  helical winding to the standard heliac has been studied experimentally. Equilibrium plasma configuration in the range  $0.7 \leq \beta \leq 1.86$  have been obtained. Analyses of the plasma pressure profiles measured by Langmuir probes in this range show good agreement between the plasma isobars and the computed vacuum magnetic surfaces; for configurations with a rotational transform  $\langle 0 \rangle$  close to unity it is necessary to take known error fields into account. When low-order rational surfaces are present, a deterioration of the plasma confinement is clearly observed. Magnetic islands, resulting from the resonance between the low-order rational surface,  $1/3$  and the  $m=2$ ,  $n=3$  vacuum field harmonics inherent in the geometry, are identified with features observed in both the plasma pressure and the floating potential files. (Author abstract) 8 refs.

**079434 DETERMINATION OF EQUILIBRIUM GLOBAL PARAMETERS FROM EXTERNAL MAGNETIC MEASUREMENTS IN JET DISCHARGE WITH AUXILIARY HEATING.** A simple procedure has been devised to extend the analysis of external magnetic measurements, using a free-boundary equilibrium solver with the additional constraint of diamagnetic measurement. The paper discusses the application of the method to ohmically and auxilially heated JET plasmas where pressure anisotropy could occur. It is shown that approximate relations commonly in use for a fast calculation of poloidal beta and internal inductance are not accurate in the case of JET. A better approximation for isotropic pressure is given. (Author abstract). 13 Refs.

Lazzaro, E. (Jet Joint Undertaking, Oxfordshire, Engl); Mantica, P. *Nucl Fusion* v 28 n 5 May 1988 p 913-918.

**079435 SELF-CONSISTENT, THREE-DIMENSIONAL EQUILIBRIUM EFFECTS ON TOKAMAK MAGNETIC FIELD RIPLE.** Self-consistent equilibrium effects on tokamak magnetic field ripple have been calculated using a three-dimensional equilibrium code. The poloidal component of the plasma current is found to amplify the magnitude of the ripple. This effect is large enough that it should be included in tokamak ignition experiment design studies. An analysis of the results separates the contribution of the Shafranov shift to the ripple modification from the contributions of other finite pressure effects. (Author abstract). 6 Refs.

Johnson, J.L. (Princeton Univ, Princeton, NJ, USA); Reiman, A.H. *Nucl Fusion* v 28 n 6 Jun 1988 p 1116-1120.

**079436 PROPERTIES OF REVERSED FIELD PINCH DISCHARGES IN OHTE WITH A POLOIDAL RING LIMITER.** A poloidal ring limiter was installed at one toroidal location in the OHTE device operated as a reversed field pinch. The ring acts as the solitary limiter beyond the smooth carbon tile vacuum vessel wall. The mere presence of the poloidal ring limiter broadens the current profile, rather than narrowing it by the reduced aperture, and raises the necessary one-turn voltage needed to sustain the current. The magnetic fluctuation frequency spectrum for both  $m=0$  and  $m=1$  poloidal modes is shifted to higher frequency in discharges with the ring limiter. The observed voltage increase is compared with that predicted by two recent edge helicity loss models. (Author abstract). 8 Refs.

La Haye, R.J. (General Atomics, San Diego, CA, USA); Schaffer, M.J.; Tamano, T.; Taylor, P.L. *Nucl Fusion* v 28 n 6 Jun 1988 p 1125-1129.

**079437 CURRENT DISTRIBUTION AND PLASMA ACCELERATION IN MPD ARCJETS WITH APPLIED MAGNETIC FIELDS.** Current distribution and plasma acceleration mechanisms in MPD arcjets with applied magnetic fields are analyzed theoretically based on induction and quasi-one-dimensional gas-dynamic equations. The finite-element method is used to obtain current distribution and magnetic field patterns. The applied magnetic fields are of diverging type ( $B_0=0$ , 0.1, 0.2 T at cathode base), and calculations are conducted in the cases of discharge currents of 1000 and 2000 A and mass flow rate of 100 mg/s for a conventional electrode geometry. From a comparison of the results calculated, if we assume the magnetic Reynolds number  $R_m$  is negligibly small or not, it is shown that current distribution on the cathode is not influenced by plasma flow and the influence of it on current distribution is bounded in the downstream region. (Edited author abstract). 9 Refs.

## Magnetoplasma

**079438 DYNAMICS OF KINK INSTABILITY IN A NON-UNIFORM MAGNETOPLASMA.** Accounting for an external electron current gradient, a set of nonlinear fluid equations governing the dynamics of kink instability in an inhomogeneous magnetized plasma has been derived. In the linear regime, the dispersion relation is analyzed and the variation of the growth rate is graphically shown. In the nonlinear regime, it is shown that a quasi-stationary solution of the mode coupling equations can be represented as a dipolar vortex. Conditions under which the latter arises are given. (Author abstract) 6 refs.

Bharuthram, R. (Ruhr-Univ Bochum, Bochum, West Ger); Shukla, P.K. *J Plasma Phys* v 38 pt 2 Oct 1987 p 309-316.

**079439 ON SCALAR SUPERPOTENTIALS FOR INHOMOGENEOUS GYROTROPIC MEDIA.** The electromagnetic field in an inhomogeneous gyrotropic medium can be represented in terms of one scalar function, the so-called superpotential. The partial differential equation of fourth order for the superpotential is derived and the connection to a simple ionospheric model is outlined. (Author abstract) 6 refs.

Weighofer, Werner (Univ of Adelaide, Adelaide, Aust). *AEU Arch Elektron Uebertrag Electron Commun* v 41 n 6 Nov-Dec 1987 p 371-372.

**079440 DYNAMICS OF A RADIATING PLASMA FLOW IN A MAGNETIC PLASMA COMPRESSOR.** A numerical simulation has been performed for the discharge in a magnetoplasma compressor of gas type with allowance for the plasma emission. The model enables one to determine the discharge dynamics and structure as well as the major radiative characteristics.

The radiation has a marked effect on the plasma parameters in the compression region, as it tends to increase the degree of compression considerably and to reduce the temperature. When one determines the emissivity of such a plasma, one needs to consider the emission spectrum. A study is made of the effects of the boundary conditions at the inlet to the acceleration channel. (Author abstract) 13 refs.

**Mathematical Models** See Also ELECTRIC SWITCHES—Magnetic Field Effects; ELECTRONS—Mathematical Models; LASERS, GAS; RADIO ASTRONOMY.

**079442 COUPLED ION-ACOUSTIC-DRIFT SOLITONS IN NONUNIFORM PLASMAS.** The effects of parallel ion motion are included in the study of drift wave solitons in a magnetized plasma with electron temperature and density gradients. A new nonlinear differential equation governing the evolution of coupled ion-acoustic-drift modes is derived. A quasi-stationary solution of the nonlinear equation is presented. It is found that the sound term can put a constraint on the speed and the profile of drift wave solitons. (Author abstract) 12 refs.

Shukla, P.K. (Ruhr-Univ Bochum, Bochum, West Ger). *Phys Scr* v 36 n 4 Oct 1987 p 644-645.

**079443 PLASMA-OPTICAL SYSTEM MODELLED USING PARTICLES.** A 'particle' model of plasma behaviour, suitable for application to the study of plasma-optical systems, has been developed. A plasma-optical system which removes macroscopic droplets from a neutralized beam of ions and electrons, produced by an arc, has been modelled and its performance has been analysed. This method will be equally effective for time-dependent fields such as occur in RF discharges used in 'plasma processing'. The variation in ion current to a substrate, where the ions deposit as a thin film, has been studied. The objective is to maximize the deposition rate whilst preventing macroscopic particles which arise at the arc from striking the film. An alternative system whose calculated transmittal rate from source to target is higher, for long mean-free-paths, is also examined. (Edited author abstract) 7 refs.

Hitchon, W.N.G. (Univ of Wisconsin, Madison, WI, USA). *J Plasma Phys* v 38 pt 1 Aug 1987 p 87-94.

**079444 POWER BALANCE MODELS FOR ROTAMAK PLASMAS.** Energy transfer processes are calculated for a range of rotamak plasmas which are modelled by equilibria with plasma pressure proportional to either the poloidal flux function or the square of this function. The latter case is more realistic, so it is used to study the conditions for which global power balance can be obtained for both the electrons and the ions. The absence of a toroidal magnetic field means that there is no neo-classical transport. Provided that the particle and energy diffusion remains classical when the plasma temperature increases, the energy confinement time is predicted to scale as  $n^{3/2} R^8$ , where  $n$  is the density and  $R$  is the radius of

the separatrix. As the plasma temperature increases, the dominant energy loss process changes from plasma recycling to electron thermal conductivity and then to ion thermal conductivity. (Author abstract) 18 refs.

**079445 ANALYTIC MODEL FOR FLOW REVERSAL IN DIVERTOR PLASMAS.** An analytic model is developed and used to study the phenomenon of flow reversal which is observed in two-dimensional simulations of divertor plasmas. The effect is shown to be caused by the radial spread of neutral particles emitted from the divertor target which can lead to a strong peaking of the ionization source at certain radial locations. The results indicate that flow reversal over a portion of the width of the scrape-off layer is inevitable in high recycling conditions. Implications for impurity transport and particle removal in reactors are discussed. (Author abstract) 8 refs.

**079446 EQUATIONS OF STATE AND IONIZATION EQUILIBRIUM OF NON-DEBYE PLASMA.** A semiphenomenological theory of the thermodynamic properties of non-Debye plasma is constructed, on the basis of dividing the states of the electron spectrum into three parts: bound states (atoms), free states, and intermediate (localized) states. This allows the thermodynamic potential of the plasma to be expressed as the sum of contributions. (Edited author abstract) 29 refs.

Kaklyugin, A.S. (Acad of Sciences of the USSR, USSR); Norman, G.E. *High Temp* v 25 n 2 Mar-Apr 1987 p 137-144.

**079447 THERMOPHYSICAL AND TRANSPORT PROPERTIES OF MULTICOMPONENT GAS PLASMAS AT MULTIPLE TEMPERATURES.** For a gas plasma, with the electrons at an elevated temperature with respect to the heavy particles temperature, a general method is presented using the rigorous kinetic theory to calculate the equilibrium composition and transport properties such as the viscosity, the thermal conductivity, the electrical conductivity, the electron diffusion coefficient and the mobility coefficient. The values for the noble gas plasma and air plasma are determined for various pressures, electron temperature up to 50,000 K and electron to heavy particles temperature ratio up to two. However, the two-temperature calculations are made only for the cases where there are no molecular species present in the gas mixture. (Author abstract) 62 refs.

**079448 TAKING ACCOUNT OF SHORT-RANGE REPULSIVE POTENTIAL IN DESCRIBING CHARGED-PARTICLE SYSTEMS.** It is shown that the term independent of the ionic charge present in the expressions for the pressure and free energy corresponding to the approximation of the second virial coefficient for the model of solid charged spheres of the same diameter  $r_0$ , like the other terms of these expressions, is a function of the plasma parameter. Conditions are found such that the expressions for the thermodynamic functions of a completely ionized system described by the model of solid uncharged spheres corresponding to the approximation of the second virial coefficient transform to the equivalent expression of the second approximation of Debye-Hückel theory, except for terms equivalent to the product of the plasma and the ratio of  $r_0$  to the Debye radius. (Author abstract) 25 refs.

**079449 MATHEMATICAL MODEL OF THE INTERACTION OF HIGH-ENERGY PASSING IONS WITH TOROIDAL PLASMA.** The Focke-Planck ki-

netic equation for high-energy ions derived in an earlier study is simplified for the motion of ions along passing trajectories. As a result, the stationary problem is reduced to a Cauchy problem for a two-dimensional parabolic equation; a numeric solution of this equation allows calculating the energy characteristics of the process of deceleration of fast ions in a background plasma. The results are relevant to tokamak plasmas. (Edited author abstract) 3 refs.

Kostomarov, D.P.; Mitrofanov, V.A. *Moscow Univ Comput Math Cybern* n 3 1987 p 1-9.

**079450 TIME-AVERAGE MODEL OF THE rf PLASMA SHEATH.** A time-averaged model of the rf plasma sheath was developed. The ion 'fluid' equations were used with a frictional force to account for ion-neutral collisions. Consideration of the collision dynamics showed that the frictional force may be taken as proportional to the square of the ion drift velocity. The sheath model was used to investigate the ion energy and flux on the electrodes of plasma reactor. The dimensionless quantity CO (collision number) was found to be important in describing the ion motion in the sheath. An analytical expression for the ion bombardment energy was derived, in terms of CO and the sheath voltage, for the range of parameter values typical of high pressure (approx. 1 torr) diode plasma etchers. An application of the model to an oxygen discharge in a parallel plate reactor was considered. (Edited author abstract) 27 refs.

**079453 MODELLING PARTICLE FORMATION AND GROWTH IN A PLASMA SYNTHESIS REACTOR.** A model for particle nucleation and growth in a thermal plasma reactor is discussed. A nondimensional form of the aerosol general dynamic equation is derived under a set of simplifying assumptions which are appropriate to plasma powder synthesis and the resulting set of equations is solved numerically. The results are converted to dimensional form for the case of iron powder, for which experimental data are available, and for silicon carbide. Calculated particle sizes increase significantly with increasing reactant concentrations and with decreasing cooling rate, although the influence of cooling rate is mainly a residence time effect. (Author abstract) 13 refs.

**079456 NUMERICAL SIMULATION OF THE PLASMA EQUILIBRIUM IN A TOKAMAK.** This paper deals with the numerical simulation of the axisymmetric equilibrium of the plasma in a Tokamak. The modelization takes into account both the Maxwell equations and the Grad-Shafranov equilibrium equation. The plasma boundary is a free boundary, defined as being the flux line which is in contact with a limiter. A weak formulation of the equations for the flux  $\psi$  of the poloidal magnetic field is given and a finite element method is then presented. Both a direct resolution for  $\psi$  in an Eulerian grid of the cross-section of the torus and an inverse formulation in terms of coordinates linked to the flux lines are given, as well as a quasi-inverse finite element technique. Several algorithms are presented for the treatment of the nonlinearities. Finally typical equilibrium configurations are calculated for the European JET Tokamak. (Edited author abstract) 25 refs.

**079459 EFFECT OF EROSION ON CONDUCTIVITY MEASUREMENTS OF A SEEDED COMBUSTION PLASMA.** The electrical conductivity of the seeded (with  $K_2CO_3$ ) combustion products of an oxy-LPG ( $C_3H_8$ ) system is measured with the help of double probes. An analytical model is developed to take into account the effect of erosion on the dimensions of the probes. The conductivity of the seeded oxy-LPG system is then evaluated by considering the effect of erosion. The values of electrical conductivity so obtained are found to be in better agreement with theoretically predicted conductivity results than those obtained without considering erosion of the probes. The effect of erosion on the conductivity values at high temperatures and high seeding is found to be as much as about 50-70%. (Author abstract) 10 refs.

**079460 NEW METHOD FOR MEASURING PLASMA POTENTIALS WITH A HIGH TIME RESOLUTION.** A new method is proposed for measuring plasma potentials in a low temperature and density plasma (electron temperature of a few ten thousands Kelvin, a density below  $10^{12} \text{cm}^{-3}$ ) with a high time resolution ( $\sim 10 \mu\text{s}$ ). An emissive problem which is heated to emit electrons into a plasma is used, and is biased automatically at the floating potential with a zero current of the probe. The validity of this method is clarified by comparing it with the conventional one. In addition, the double layer is formed by injecting an ion beam into an electron sheath, and a formation process is studied by measuring the time variation of the potential profile. (Author abstract) 13 refs.

**079461 FAST IDENTIFICATION OF PLASMA BOUNDARY AND X-POINTS IN ELONGATED TOKAMAKS.** A new method of identifying the plasma boundary and X-points in elongated tokamaks is presented. The method uses a finite element representation of the plasma current. It is applied to a number of computed equilibria with various shapes and elongations up to  $b/a=3$ . Errors in the flux, magnetic field and coil current measurements are simulated by adding random perturbations to the values obtained from the equilibrium code. The method appears to be sufficiently accurate and fast for real-time shape control. (Author abstract) 12 refs.

**079462 LASER DOPPLER ANEMOMETRY UNDER PLASMA CONDITIONS. PART I. MEASUREMENTS IN A D.C. PLASMA JET.** A study is presented on the use of laser Doppler anemometry (LDA) techniques for the measurement of the gas and particle velocities under plasma conditions. Experimental data is presented for a d.c. plasma jet in which alumina particles are injected under different operating conditions. The results reveal that the plasma velocity at the exit of the jet is of the order of 200-300 m/s. The intensity of turbulence is as high as 30 to 40% in the free shear layer and the particle velocity distribution is shown to be asymmetric, with particle dispersion in the plane of injection considerably more important than that in the perpendicular direction. The average particle velocity depends on the composition of the plasma gas, the torch current, and power. (Author abstract) 27 refs.

Lesinski, J. (Univ de Sherbrooke, Sherbrooke, Que, Can); Boulos, M.I. *Plasma Chem Plasma Process* v 8 n 2 Jun 1988 p 113-132.

**079463 LASER DOPPLER ANEMOMETRY UNDER PLASMA CONDITIONS. PART II. MEASUREMENTS IN AN INDUCTIVELY COUPLED R.F. PLASMA.** Laser Doppler anemometry is used for the measurements of the plasma and particle velocity profiles

in the coil region of an inductively coupled r.f. plasma. Results are reported for a 50 mm i.d. induction plasma torch operated at atmospheric pressure with argon as the plasma gas. The oscillator frequency is 3 MHz and the plate power is varied between 4.6 and 10.5 kW. Plasma velocity measurements are obtained using a fine carbon powder as a tracer. Measurements are also given for larger silicon particles ( $d_p=33 \mu\text{m}$  and  $\sigma=13 \mu\text{m}$ ) centrally injected into the discharge under different operating conditions. (Author abstract) 10 refs.

**079464 STEEP GRADIENT AND PEDESTAL OF ELECTRON PROFILES IN H-MODE JFT-2M PLASMA.** The steepening of the density gradient and the pedestal of the edge temperature inside the separatrix (the most outward magnetic surface limiting a plasma) were observed in tokamak H-mode phase. The plateau region on the pedestal corresponds to the region of greatest increase of the density at the beginning of the H-mode transition, and a hollow profile is formed. This is due to a transport barrier, which reduces the effect of enhanced transport by internal disruption. (Author abstract). 15 Refs.

**079465 MEASUREMENTS OF ENERGY DISTRIBUTIONS IN ECR PLASMA.** The electron energy distribution is measured in an ECR device for  $H_2$  and  $N_2$  plasmas as a function of pressure. The maximum measurable energy and the high-energy tail increase with decreasing pressure. However, the energy distribution at the high-energy part progressively departs from a Maxwellian shape as the pressure is increased. The electron temperature obtained from the low-energy part increases with decreasing pressure. The positive ion temperature is of the order of a few eV and increases with the electron temperature. A mechanism of ion acceleration should exist. (Author abstract). 16 Refs.

**079466 MEASUREMENTS OF NEGATIVE POTENTIALS IN A TANDEM MIRROR EXPERIMENT.** Negative plasma potentials as large as  $-400 \text{ V}$  were measured in the magnetic fusion experiment Tandem Mirror Experiment-Upgrade (TMX-U). Normally, a plasma confined by an open ended magnetic field produces a positive potential. To measure the negative potentials, neutral beams were injected into the plasma region at angles within the loss cone. The greatest negative potentials were observed after the electron cyclotron heating power was turned off but while energetic ions were still being introduced into the plasma with large-angle neutral beams. These negative potentials are explained in terms of thermal ions electrostatically trapped by long lived, hot, mirror confined electrons. (Author abstract). 9 Refs.

## Military Applications

**079471 TEMPERATURE ESTIMATES FOR A FREE FLOWING RAILGUN PLASMA.** In-bore spectroscopic observations of a free-flowing plasma for wavelengths between 3000 and  $6250 \text{ \AA}$  were made for a series of railgun firings. In this report the experimental arrangement for the series is described and the results are presented. Atomic species present in the plasma are identified from absorption and emission spectra. Calculations of the degree of ionization of these species are then used to produce a temperature estimate between  $11 \times 10^3 \text{ K}$  to  $25 \times 10^3 \text{ K}$  for the railgun plasma. A comparison of theoretical values of the plasma electrical conductivity with values obtained from muzzle voltage records indicates that the peak plasma temperature is approximately  $11 \times 10^3 \text{ K}$ , which is consistent with estimates obtained from the spectra. (Author abstract) 41 refs.

Clark, G.A.; Kowalenko, V. *Rep Mater Res Lab Aust* 1054 Jun 1987 44p.

**079472 EXPERIMENTAL INVESTIGATION OF A THREE-STAGE RAILGUN INCORPORATING PUFF-SWITCHING.** A sequence of four firings of a 2.4 m long, 10 mm square bore railgun is described and analyzed. The railgun comprised an injection stage, a breech power source and a second power source which was connected by a 'puff-switch'. The report deals with the puff-switching results, distribution of current in the plasma, the proportion of projectile kinetic energy due to plasma expansion forces as compared to electromagnetic forces, the correlation of rail damage with current and plasma length, and velocity limitation according to the ablation model. (Author abstract) 15 refs.

Sadedin, D.R.; Stainsby, D.F. *Rep Mater Res Lab Aust* 1056 May 1987 70p.

**079473 RAILGUN AND ITS POWER SOURCE.** Investigations into the propulsion mechanisms of railguns and into the power source requirements of railguns are reported. Power sources based upon rotating machines, capacitors and explosives are reviewed and a new method based upon batteries and pulse transformers is identified. The battery and pulse transformer method is studied in detail. (Author abstract) 160 refs.

## Optical Properties

**079474 OPTICAL PROPERTIES OF AIR PLASMA AT HIGH TEMPERATURES. CONTINUOUS SPECTRUM: BASIC PROCESSES, CALCULATION TECHNIQUES.** This paper describes an extension of the temperature range to  $3 \times 10^4$  K, as well as a check of the accuracy of previously employed methods of calculating the cross-sections of elementary radiation processes by comparison with a restricted set of recently performed standard calculations, and demonstrates the acceptability and advantages of the techniques employed. The present publication consists of two parts. In the first part, the current status of studies into the cross-sections of radiation processes in high-temperature plasma is analyzed, and the methods of calculating the contribution made by individual processes are refined. The second part describes the results of calculation of the total photoabsorption cross-sections for different ions of nitrogen and oxygen 142 refs.

**079476 COLLECTIVE EFFECTS AND ANOMALOUS CONDUCTIVITY IN A NONIDEAL CURRENT-CARRYING PLASMA. PHYSICAL MODEL. STRATIFICATION OF A CURRENT-CARRYING CONDUCTOR.** The possibility of a buildup of superthermal plasma oscillations in a nonideal plasma is discussed for the example of experiments on the generation of a dense plasma by the method of isobaric heating of conductors. A physical model, which explains from a unified viewpoint the appearance and evolution of strata accompanying an 'electrical explosion' and the appearance

of anomalous electrical conductivity in a nonideal current-carrying plasma, is proposed. Numerical solutions for the initial preplasma stage of the discharge are presented and discussed. (Author abstract) 26 refs.

Batenin, V.M. (Acad of Sciences of the USSR, USSR); Berkovskii, M.A.; Valuev, A.A.; Kurilenkov, Yu.K. *High Temp* v 25 n 2 Mar-Apr 1987 p 145-151.

**079477 COLLECTIVE EFFECTS IN AND ANOMALOUS CONDUCTIVITY OF A NONIDEAL CURRENT-CARRYING PLASMA. EVOLUTION OF STRATA AT THE PLASMA STAGE OF THE DISCHARGE. BUILDUP OF SUPERHERMAL LANGMUIR NOISE.** The possibility of the buildup of nonequilibrium (superthermal) plasma oscillations in a nonideal plasma is discussed for the example of experiments on isobaric Joule heating of wires. A model describing the plasma stage of a discharge is proposed and realized numerically. A possible mechanism for the appearance and character of the turbulent state of a nonideal plasma is studied. It is concluded that turbulent heating of nonideal strongly-collisional plasma is possible. (Author abstract) 22 refs.

**079478 SELF-SUSTAINED OSCILLATIONS IN THE DIVERTOR PLASMA.** A simple analytical model for a high recycling edge plasma, which relies on the presence of a small parameter - the ratio of the particle flows crossing the magnetic field to those impinging on the target - is proposed. The concept of a one-dimensional steady state (OSS) is introduced as a zero approximation in the small parameter. The mean number density  $N^-$  of the particles - ions plus neutrals - in the magnetic flux tube is chosen as the most representative and convenient parameter of the problem. The OSS is shown to be ambiguous in a certain  $N^-$  range for sufficiently high values of the energy flow entering the scrape-off layer from the bulk plasma. This ambiguity is confirmed by 1-D calculations. (Edited author abstract) 24 refs.

**079479 ON THE INFLUENCE OF DISSIPATIVE PROCESSES ON THE SPACE-TIME DYNAMICS OF INSTABILITY IN A PLASMA.** When electromagnetic waves and beams of charged particles propagate in a plasma, instabilities appear with the excitation of intercoupled oscillations and, correspondingly, a pumping wave or beam of particles by the space-time synchronism conditions. The level of energy dissipation of the excited oscillations and the boundedness of the system influence the development of instabilities. This paper discusses the unique features of the variation of the space-time dynamics of instabilities of this type because of the presence of dissipative processes in the system. We restrict our consideration to the simplest instabilities in the linear approximation in terms of the amplitudes of the excited oscillations. 6 refs.

**079483 ON SHIFTING OF PLOWED PLASMA TO BACK OF CURRENT SHEATH IN IMPLOSION PHASE OF THETA-PINCH.** In order to study a phenomenon that the plowed plasma had shifted to the back of the current sheath region in the implosion phase of a theta pinch, computer simulations were performed by using MHD equations consisting of electrons, ions and atoms. The simulations clarified the mechanism by which the plasma plowed in front of the current sheath had shifted to the back of the sheath. The phenomenon is caused by a decrease in the electron temperature or a resistivity enhancement due to inelastic collisions, especially excitation collisions, of electrons with atoms. The shifted plasma still implodes with the  $E \cdot 4 \times B$  drift velocity. The charge exchange has little effect on the phenomenon. (Author abstract) 12 refs.

Ogi, Sukeomi (Kyushu Univ, Fukuoka, Jpn); Shiratani, Masaharu; Takamatsu, Masahiro; Watanabe, Yukio. *Jpn J Appl Phys Part 1* v 26 n 8 Aug 1987 p 1334-1341.

**079484 SPHERICAL PINCH.** This is essentially a review article covering several years of work on the spherical pinch (SP) concept of plasma formation and containment. Central to this concept is the creation of a hot plasma in the center of a sphere, plasma which is then compressed by strong imploding shock waves launched from the periphery of the vessel. In a pilot experimental program of modest initial condenser bank energy (approx. 1 kJ), we find that the instantaneous energy deposition in the central plasma can lead to temperatures of the order of 2 Kev, in agreement with the prediction of the Braginskii resistivity for such a plasma, and with the

relation to the velocity of the diverging shock wave generated by the sudden deposition of energy into this plasma. (Edited author abstract) 18 refs.

**079485 GAS-PUFF Z PINCHES WITH STRONG AXIAL MAGNETIC FIELDS.** Ultrahigh axial magnetic fields have been compressed and measured in a gas-puff Z pinch. A 0.5-MA, 2-cm-radius annular gas-puff Z pinch with a 3-minute repetition rate was imploded radially onto an axial seed field, causing the field to compress. Axial magnetic field compressions up to 180 and peak magnetic fields up to 1.6 MG were measured. Faraday rotation of an argon laser (515.4 nm) in a quartz fiber on axis was the principal magnetic field diagnostic. Other diagnostics included a nitrogen laser interferometer, x-ray diodes, and magnetic field probes. The method of compressing axial fields in a gas-puff Z pinch is extrapolable to the order of 100 MG. Scaling laws are presented. Potential applications of ultrahigh axial fields in Z pinches are discussed for x-ray lasers, inertial confinement fusion, and collimated sources of gamma radiation. (Edited author abstract) 9 refs.

**079486 GENERATION OF A LARGE SWELLING IN THE SPATIAL MAGNETIC FIELD PROFILE NEAR THE COIL AXIS OF A THETA PINCH.** A large magnetic field swelling near the coil axis in a theta pinch with low discharge energy was investigated in detail by changing the gas-fill pressure, the kind of gas and intensity of the applied magnetic field. Under the experimental conditions, the maximum magnetic field around the axis amounted to more than three times the applied field. It was experimentally clarified that the shifting of the plowed plasma to the back of the current sheath in the implosion phase is essential for the phenomenon and that the amplitude of the field around the axis can be explained by the flux trapped by the shifted plasma. (Author abstract) 13 refs.

**079487 STUDIES OF A VERTICALLY ELONGATED SCREW PINCH AND A TOROIDAL Z-PINCH.** Two types of toroidal pinch, a vertically elongated screw pinch and a toroidal Z-pinch based on spontaneous generation of toroidal field flux, are described. The equilibrium of a non-circular screw pinch plasma is numerically examined. A limiting beta is obtained from optimization of the plasma cross section and is 18% for a plasma of elongation of 2. The equilibrium of a toroidal Z-pinch plasma, with toroidal field and plasma current profiles vanishing at the boundary, is also examined. (Edited author abstract) 75 refs.

**079488 OBSERVATIONS OF HIGH ION TEMPERATURES IN A REVERSED FIELD PINCH PLASMA.** The ion temperature,  $T_i$ , of reversed field pinch plasmas was measured by means of a neutral particle energy analyzer (NPA) and by measuring the Doppler broadening of a CV line (227.091 nm) in TPE-IRM. The results obtained by these two methods agree within the experimental error. The measured  $T_i$  is about 600-800 eV and is higher than  $T_{e0}$ , the central electron temperature measured by Thomson scattering. This fact cannot be explained by the classical ion heating mechanism and suggests that an anomalous ion heating mechanism exists in the RFP plasma. This high  $T_i$  seems to correspond to the bulk of the ions.  $T_i$  increases with the plasma current over the range of 55-100 kA. (Author abstract) 19 refs.

**079489 EFFECT OF INSULATOR GAP ON THE PERFORMANCE OF A REVERSED-FIELD PINCH PRODUCED IN A THICK METAL CHAMBER.** A reversed-field pinch (RFP) plasma which has characteristics typical of that produced in a conventional thin metal liner has been obtained in the STE-1(M) device. It uses a 3.4 mm-thick stainless-steel chamber with four insulators for the application of the toroidal voltage, along with the aided self-reversal mode for setting up the RFP configuration. Displacement of the center-of-current channel at the insulator gap was twice as large as that far from the gap. This local displacement could be reduced by the vertical field. Optimization of the vertical field resulted in a 20% decrease of the sustaining voltage. (Author abstract) 8 refs.

**079490 STABILITY PROPERTIES OF A TOROIDAL z-PINCH IN AN EXTERNAL MAGNETIC MULTIPOLE FIELD.** MHD stability of  $m=1$ , axisymmetric, external modes of a toroidal z-pinch immersed in an external multipole field (Extrap configuration) is studied. The description includes the effects of a weak toroidicity, a non-circular plasma cross-section and the influence of induced currents in the external conductors. It is found that the non-circularity of the plasma cross-section always has a destabilizing effect but that the  $m=1$  mode can be stabilized by the external feedback if the non-circularity is small. (Author abstract). 10 Refs.

**079491 FINITE ELEMENT STUDY OF A CURRENT-CARRYING PINCH IN A STRONG LONGITUDINAL MAGNETIC FIELD.** A linear finite element method has been applied to the analysis of the stability of a current carrying pinch in a strong magnetic field. The two cases of fixed and free boundaries are studied extensively for a wide range of values for the two parameters  $m$  and  $k$ . The growth rate of instabilities has been calculated numerically. It has been shown that the numerical results, for which corresponding analytical results are available, are in good agreement with them. There are, however, some new numerical results which are not confirmed analytically but represent the physics of the problem property. (Author abstract). 6 Refs.

Zaki, Sherif I. (Suez Canal Univ, Ismailia, Egypt). *Phys Scr* v 37 n 6 Jun 1988 p 885-890.

**079492 ON THE APPLICATION OF THE IDEAL MAGNETOHYDRODYNAMIC LINEAR EIGENVALUE EQUATION TO THE Z-PINCH.** A study of the ideal magnetohydrodynamic linear eigenvalue spectrum for free-boundary modes in the Z-pinch is presented. The application of a variational method to estimate eigenvalues is described and limitations imposed by the nature of the spectrum are discussed. An analytic expression for the long-wavelength  $m=0$  growth rate is derived. (Author abstract). 16 Refs.

**079493 STARTUP OF REVERSED FIELD PINCHES AND CURRENT RAMPING USING DYNAMO ACTION.** This paper discusses the startup of a reversed-field pinch (RFP) and some of the different modes by which a final RFP state can be reached. RFP startup differs from startup of other toroidal devices such as the tokamak because of the spatial variations of toroidal flux and the reversal of the toroidal magnetic field in the outer region of the plasma required in the final state. The purpose of this paper is to address the techniques used to reduce the voltage and volt-second (V·s) requirements

during an RFP startup - a subject of high importance in the design of the next-generation RFP experiments. 40 Refs.

**079498 STUDY OF SURFACE-WAVE-PRODUCED PLASMA COLUMN LENGTHS.** An experimental description of the length of cylindrical plasma columns produced and sustained by a weakly damped surface wave is presented. A general experimental law for the column length is obtained that depends on the operating parameters in a wide range of discharge conditions. This general empirical law can be deduced theoretically from similarity laws already known to apply to such plasmas. (Author abstract) 16 refs.

Sola, A. (Univ de Cordoba, Cordoba, Spain); Cotrino, J.; Gamero, A.; Colomer, V. *J Phys D* v 20 n 10 Oct 14 1987 p 1250-1258.

**079499 WAVEGUIDE SURFATRON: A HIGH POWER SURFACE-WAVE LAUNCHER TO SUSTAIN LARGE-DIAMETER DENSE PLASMA COLUMNS.** A novel microwave structure which allows a plasma column to be sustained through the propagation of an electromagnetic surface wave is investigated. This plasma source is analysed in terms of a simple equivalent circuit which correctly predicts the transfer of power from the microwave generator to the plasma as a function of the tuning system of the launcher; it further shows that such a microwave structure is the waveguide equivalent of the surfatron. This device seems a particularly well adapted substitute for the surfatron at 2.45 GHz (or higher frequencies) when there is a need to operate at high (> 500 W) microwave power levels or with large ( $\leq 15$  mm) tube diameters. (Author abstract) 12 refs.

**079500 FUNDAMENTAL PLASMA EMISSION INVOLVING ION SOUND WAVES.** The theory for fundamental plasma emission by the three-wave processes  $L \pm S \rightarrow T$  (where L, S and T denote Langmuir, ion sound and transverse waves, respectively) is developed. Kinematic constraints on the characteristics and growth lengths of waves participating in the wave processes are identified. In addition the rates, path-integrated wave temperatures, and limits on the brightness temperature of the radiation are derived. (Author abstract) 14 refs.

Cairns, Iver H. (Univ of Sydney, Aust). *J Plasma Phys* v 38 pt 2 Oct 1987 p 169-178.

**079501 SECOND HARMONIC PLASMA EMISSION INVOLVING ION SOUND WAVES.** The theory for second harmonic plasma emission by the weak turbulence (or random phase) processes  $L + L \pm S \rightarrow T$ , proceeding in two three-wave steps,  $L \pm S \rightarrow L'$  and  $L + L' \rightarrow T$ , where L, S and T denote Langmuir, ion sound and electromagnetic waves, respectively, is developed. Kinematic constraints on the characteristics and growth lengths of waves participating in the wave processes, and constraints on the characteristics of the source plasma, are derived. Limits on the brightness temperature of the radiation and the levels of the  $L'$  and S waves are determined. Expressions for the growth rates and path-integrated wave temperatures are derived for simple models of the wave spectra and source plasma. (Author abstract) 15 refs.

Cairns, Iver H. (Univ of Iowa, Iowa City, IA, USA). *J Plasma Phys* v 38 pt 2 Oct 1987 p 179-198.

**079502 THIRD AND HIGHER HARMONIC PLASMA EMISSION DUE TO RAMAN SCATTERING.** The theory for third and higher harmonic plasma emission by the weak turbulence (or random phase) process  $L + T' \rightarrow T$  (where L denotes a Langmuir wave, and T and T' denote transverse waves) is developed. Kinematic constraints on the characteristics and growth lengths of waves participating in the wave processes are identified. The cases of L waves produced either directly by a streaming instability, or by the decay  $L \rightarrow L' + S$  (S is an ion sound wave) of L waves generated by a streaming instability, are considered. Limits on the brightness temperature of the radiation are determined, and expressions for the growth rate and path-integrated wave

temperatures are derived. (Author abstract) 16 refs.

Cairns, Iver H. (Univ of Sydney, Aust). *J Plasma Phys* v 38 pt 2 Oct 1987 p 199-208.

**079503 METAL-PLASMA SOURCE.** A metal-plasma source is described in which plasma fluxes are generated by semi-self-maintained vacuum discharge in vapors of the working material, which is evaporated from a water-cooled crucible-anode. A cell with crossed magnetic and electric fields is used for additional ionization of the plasma fluxes, which increases the degree of their ionization to 40-65%. The source is especially effective for metallization of dielectric substrates. The use of an additional-ionization cell increased by a factor of 5-8 the adhesion strength of Ni films to polykor substrates. The rate of Ni-film deposition was 0.1-1.0 nm/sec. The plasma source has been used to produce films of Cu, Cr, Ni, Ti, Mo, C, and W with thicknesses of 0.1-2.0  $\mu$ m. (Author abstract) 6 refs.

**079504 ERZEUGUNG VON MIKROWELLEN-PLASMA IN GROSSEN ENTLADUNGSRAEUMEN.** [Generation of Microwave Plasma in Large Discharge Cavities]. In the application of plasmas to thin film technology, large discharge spaces are necessary. Methods of plasma excitation by microwaves are presented and fundamental principles for the design of discharge cavities are explained. The reflection of the microwaves on plasmas is then considered. (Translated author abstract) 14 refs. In German.

Hammer, Klaus. *Wiss Z Tech Univ Karl Marx Stadt* v 29 n 2 1987 p 256-262.

**079505 CHARACTERIZATION OF AN ANALYTICAL THETA-PINCH PLASMA GENERATED WITH A UNIDIRECTIONAL CAPACITIVE DISCHARGE.** The plasma produced by a high-current capacitive discharge through a graphite fiber bundle is compressed by a magnetic field coaxial with the plasma. The magnetic field is generated by the plasma current in a large coil surrounding the plasma. The field induces an azimuthal ( $\theta$ ) current in the plasma. This current couples with the external magnetic field and produces a radial Lorentz force which reduces the rate of plasma expansion. A diode shunt in the capacitive discharge circuit is used for the generation of a unidirectional discharge current. This arrangement eliminates zero-crossings of the discharge current and thus increases the effectiveness of the magnetic field in controlling the radiative properties of the plasma. Design features of the discharge circuit are presented. (Edited author abstract) 21 refs.

## Radiation Effects

**079508 OBSERVATION OF THREE-HALF HARMONIC RADIATION FROM PLASMAS IRRADIATED BY A 0.26  $\mu$ m WAVELENGTH LASER.** Time-integrated measurements have been made of three-half harmonic light energy emitted from 0.26  $\mu$ m laser-produced plasmas. The main results are the experimental dependence of  $3/2\omega_0$  conversion efficiency and threshold on electron density-profile shape. Various density profiles are achieved by irradiating different kinds of target; their shapes are estimated with the help of two-dimensional hydrodynamic simulations. (Author abstract) 24 refs.

Labaune, C. (Ecole Polytechnique, Palaiseau, Fr); Fabre, E.; Bonnaud, G. *J Plasma Phys* v 38 pt 3 Dec 1987 p 445-451.

**079509 INDUCED RECOMBINATION AND THE POSSIBILITY OF AMPLIFYING RADIATION IN A PLASMA.** A study is made of induced photorecombination caused by collisions of electrons with ions (atoms) of a plasma in the presence of a strong electromagnetic field. A negative coefficient of absorption of the radiation is obtained for the recombination of an electron in the discrete state, with subsequent spontaneous radiation decay of the electron. If the autoionized state is present in the continuous spectrum of an atom, then taking photoabsorption into account means that for narrow electron distribution functions the absorption coefficient can be either positive or negative. (Author abstract) 10 refs.

**079510 ELECTRON FLUID EQUATIONS AND MAGNETIC FIELD GENERATION IN LASER-IRRADIATED COLLISIONAL PLASMAS.** The results of a previous paper are used for deriving the electron fluid equation of laser-irradiated collisional plasmas as well as the equations which govern the magnetic field generation in these media. It is shown that these equations involve various collisional contributions which can be exactly calculated at each order for any electron-ion interaction law, and that they enable us to recover, as special cases, the results given in other works. These methods provide a self-consistent theory of transport phenomena in high Z plasmas, in which the background state is generally non-Maxwellian and evolves on a slow time scale determined by the electron heating process. The full calculations are given for the Coulomb law in a particular case, and the results so obtained are compared to those derived from the Krook model. (Author abstract) 12 refs.

**Sheaths** See Also ANTENNAS, CYLINDRICAL—Measurements.

**079513 GENERAL SOLUTION CONDITION FOR COLLISIONLESS SHEATHS.** A general solution condition for collisionless sheaths is developed. Previous work has assumed that the Bohm criterion or the generalized Bohm criterion ensures a self-consistent sheath solution. This paper shows that for non-monotonic collisionless sheath structures, such as double sheaths containing trapped ions, the generalized Bohm criterion is a necessary but not a sufficient condition. The general solution condition developed is always sufficient and the generalized Bohm criterion is shown to be special case of it. The general solution condition is applied to a double emitter sheath containing trapped ions. Both the sheath structure and the generalized Bohm speed depend on the amount of trapped ions. Thus collisional effects may dominate the structure of a presumably collisionless sheath through the trapping mechanism and the collisional pre-sheath which determines the low-energy ion component entering the collisionless sheath. (Edited author abstract) 10 refs.

Main, Geoffrey L. (Georgia Inst of Technology, Atlanta, GA, USA); Lam, S.H. *J Plasma Phys* v 38 pt 2 Oct 1987 p 287-300.

**079514 FIELD-DRIVEN ION MIGRATION AGAINST DEAD-STOP COLLISIONAL BRAKING.** The steady-state migration of ions, driven by a uniform electric field against full-stop collisions, is investigated in some detail. The required phase-space distribution is obtained very easily from Boltzmann's equation together with explicit recognition of energy conservation and population balance for the stagnant ion pool. Numerical consequences of the solution obtained here reveal that both ion density and average kinetic energy relax to their terminal values within just a few mean free-path lengths. Such modest scaling of plasma-sheath extent evidently carries a beneficial implication for the technological ease with which surface properties (such as metal corrosion resistance and hardness) remain open to improvement via ion bombardment. (Edited author abstract)

## Simulation

**079516 FAST MULTIPOLE METHOD FOR GRIDLESS PARTICLE SIMULATION.** The numerical solution to N-body problems in gravitation or electrostatics has traditionally been obtained via particle-in-cell methods (PIC) since direct evaluation of all pairwise interparticle forces, requiring  $\mathcal{O}(N^2)$  operations, is too expensive. Recently, hierarchical solvers, which use tree data struc-

tures and lumped-force approximations, have made gridless simulations feasible in  $\mathcal{O}(N \log N)$  operations. In this paper, we explore the use of the fast multipole method (FMM) - a highly accurate order  $\mathcal{O}(N)$  algorithm - in particle simulations. We briefly describe the FMM and its relation to other methods. Technical considerations of gridless simulations such as discrete particle fluctuations, sampling errors and boundary conditions are discussed and compared with PIC methodology. Examples of electrostatic simulations in plasma physics are presented. (Author abstract) 13 refs.

## Space Charge

**079519 REMOVAL OF SINGULARITIES IN THE HYDRODYNAMIC DESCRIPTION OF PLASMAS INCLUDING SPACE-CHARGE EFFECTS, SEVERAL SPECIES OF IONS AND NON-VANISHING ION TEMPERATURE.** The hydrodynamic or gas-dynamic theory of plasma including space-charge effects and several species of ions involves singular points within the plasma if the pressure and inertia of the charged particles are taken into account simultaneously. These singularities, which occur if the mean velocity of one of the species of particles reaches the sound velocity, can be removed. The required smoothing conditions lead to a well determined, non-linear eigenvalue problem for the concentrations of the various species of ions. Three methods are elaborated to calculate the eigenvalues and to obtain smooth solutions. It is shown that even under quasi-neutral conditions similar mathematical problems occur if the plasma contains several species of positive ions. The methods described can be applied to plasmas in low-pressure discharges, in hollow cathodes and near electrodes and to fusion plasma. (Author abstract) 31 refs.

## Spectroscopic Analysis

**079520 EFFECT OF PLASMA OPACITY ON THE DOPPLER-FREE POLARIZATION SPECTRUM IN A HYDROGEN PLASMA.** In a low-density hydrogen plasma, the saturation behavior of the  $H_{\alpha}$  line emission has been studied by Doppler-free polarization spectroscopy with a pulsed high-power tunable laser. Spectral profiles of the Doppler-free fine structure components of the  $H_{\alpha}$  line were found to be largely distorted by the effect of reabsorption in the plasma. A simple calculation of the spectral profiles, while taking into account of the effect of the plasma opacity in the saturation conditions, is in good agreement with the experimental results. (Author abstract) 7 refs.

**079521 SPECTROSCOPIC STUDY OF IMPURITY BEHAVIOUR IN NEUTRAL BEAM HEATED AND OHMICALLY HEATED TFTR DISCHARGES.** This paper presents a detailed analysis of extreme UV and visible impurity emissions from TFTR plasmas on a movable graphite limiter with up to 5.6 MW of beam power. It provides reference documentation of both ohmically heated and standard beam heated (L-mode confinement) discharges. The techniques used to analyse extreme UV and visible impurity emissions from TFTR plasmas are discussed in detail. As a further focus, variations in impurity behaviour with density and beam power in discharges with 2.2 MA plasma current ( $I_p$ ) and 4.7 T toroidal field ( $B_T$ ) are considered. 28 refs.

**079522 PRINCIPLES OF SPECTROSCOPIC DIAGNOSTICS OF PLASMA WITH OSCILLATING ELECTRIC FIELDS.** The author developed a method for performing quasiloocal measurements of the parameters of the QEF Quasimonochromatic Electric Fields in the region of a strong field (for observations integrated over the line of sight), based on the adiabatic theory of satellites (ATS) of dipole-forbidden lines of helium-like or lithium-like atoms. The standard three-level scheme was studied: a quantum system consisting of two close-lying levels 1 and 2, only one of which is linked by a dipole transition with a distant third level. Under the action of a QEF two satellites of the dipole-forbidden line appear in the spontaneous emission spectrum of such a system in addition to the dipole-allowed line (with intensity  $I_A$ ). The main part of the theory consists of solving a fundamental nonlinear-optics problem: the problem of the quasienergy states of a three-level system of a very general form in a strong or high-frequency field. The author points out that the analytic solution of the fundamental problem of the QS of a three-level system in a strong QEF, and developed in this work is not only a new division of the nonlinear theory of satellites, but it also extends the possibility of active (for example, laser fluorescence) diagnostic methods. 26 refs.

**079523 DETERMINATION OF ION TEMPERATURE AND TOROIDAL ROTATION VELOCITY VIA CHARGE-EXCHANGE RECOMBINATION SPECTROSCOPY.** In JFT-2M plasmas spatially and temporally resolved ion temperature and toroidal rotation velocity were determined by measuring the Doppler-broadened profiles of spectral lines excited by charge-exchange recombination reaction between the neutral hydrogen beam ( $H^0$ ) and fully stripped ions ( $H^+$ ,  $C^{6+}$ ). The obtained ion temperature was in agreement with that measured by the neutral particle analyzer (NPA). These experimental results indicate that the

charge-exchange recombination spectroscopy (CXRS) method is a powerful technique to measure hot and dense plasmas. (Author abstract). 20 Refs.

**079524 DETERMINATION OF THE ELECTRIC FIELD STRENGTHS IN DEUTERIUM FROM SATELLITE STRUCTURE OF BALMER LINES.** In a linear magnetoplasma with  $n_e \leq 5 \times 10^{18} \text{ m}^{-3}$  microwaves with frequency  $f = 34.8 \text{ GHz}$  and power  $P \leq 100 \text{ kW}$  were focussed with a quasi-optical horn-lens system. The profiles of the deuterium lines  $D_\beta$ ,  $D_\gamma$ , and  $D_\delta$  were recorded from the focus. The profiles show a satellite structure which is generated by the rf electric field. Beside the first order satellites which can be resolved from the main line, even second order satellites were detectable. Comparing the satellites' intensities with theory it is possible to determine the electric field strength in the focus. Due to a sensitive dependence of the satellites' intensities upon the polarization direction one can also determine an unknown polarization direction. (Author abstract). 14 Refs.

**079527 OPTICAL EMISSION SPECTROSCOPY OF  $\text{CF}_4 + \text{O}_2$  PLASMAS USING A NEW TECHNIQUE.** In this study a Cu rod is inserted into the plasma, and the rod potential is altered from the ground potential to a negative potential with a frequency of 20 Hz. The emission spectra from a  $\text{CF}_4 + \text{O}_2$  plasma are measured. A small amount of Ar gas and/or  $\text{N}_2$  gas is added and the output signal of the lock-in amplifier is adjusted to zero for either the Ar emission line or the  $\text{N}_2$  emission line. In a fluorine-contained plasma the F emission intensity normalized by the Ar one has been widely used in order to obtain the F density. This validity is confirmed by the present experiment. It is also confirmed that the CO emission intensity normalized by that of  $\text{N}_2$  is proportional to the CO density. The metastable states play an important role in the optical emission intensities of CO and  $\text{N}_2$  molecules. (Edited author abstract) 13 refs.

**079528 STRUCTURALLY INVARIANT PLASMAS.** It is shown that it may be possible to operate devices in which plasmas are magnetically confined in such a way that the structure of the configuration remains constant during the discharge, i.e. the space and time variables are separable. Since MHD stability depends on structure only, it may be possible to realize circumstances under which the plasma is MHD stable throughout the discharge. Separation of the variables is possible only for certain functional forms of the appropriate transport coefficients, among which are the classical transport coefficients. A simple case where separation is possible has been calculated numerically and it appears that MHD stable configurations are among the solutions. (Author abstract) 2 refs.

**079530 SEARCH FOR ION TEMPERATURE GRADIENT DRIVEN ELECTROSTATIC HYDRODYNAMIC INSTABILITY IN TOKAMAKS.** The ion temperature gradient drive electrostatic instability in tokamak magnetic geometry has been investigated numerically in terms of a generalized ion density moment. For typical tokamak parameters (ratio between the density gradient scale length and the major radius,  $\epsilon_0 = L_n/R$ , about 0 (0.1) and  $T_i \approx T_e$ ) the search for rapidly growing instabilities of a hydrodynamic nature has been unsuccessful, even with the ion temperature gradient relative to the density gradient,  $\eta_i = d(\ln T_i)/d(\ln n_i)$ , as large as six. (Author abstract) 19 refs.

**079531 IDEAL MHD STABILITY PROPERTIES OF PRESSURE DRIVEN MODES IN LOW SHEAR TOKAMAKS.** The role of shear in determining the ideal MHD stability properties of tokamaks is discussed. In particular, the effects of low shear within the plasma upon pressure driven modes are assessed. The standard ballooning theory is shown to break down as the shear is reduced, and the growth rate is shown to be an oscillatory function of  $n$ , the toroidal mode number, treated as a continuous parameter. The oscillations are shown to depend on both the pressure profile and the safety factor profile. When the shear is sufficiently weak, the oscillations can result in bands of unstable  $n$ -values, which are present even when the standard ballooning theory predicts complete stability. These instabilities are named 'infernal modes'. The occurrence of these instabilities at integer  $n$  is shown to be a sensitive function of the  $q$ -axis, raising the possibility of a sharp onset as the plasma parameters evolve. **079534 NUMERIC STUDY OF STEADY STATES IN PLASMA.** A model of description of quasi-steady states of plasma with a finite conductivity is constructed. A method of calculation of the characteristics of these states is suggested which does not make use of variable inversion. The results of numeric simulations of high- $\beta$  steady states in INTOR are described. (Author abstract) 6 refs.

Zotov, I.V. *Moscow Univ Comput Math Cybern* n 2 1987 p 44-50.

**079535 CYCLOTRON INSTABILITY OF THE SLOW EXTRAORDINARY WAVE IN A MAGNETOACTIVE PLASMA.** The dipole approximation is applied to the kinetic instability in longitudinally propagating whistlers and the Z mode at frequencies below the nonrelativistic electron gyrofrequency, which is due to a group of fast electrons in a magnetic trap. Numerical calculations are used to analyze the effects from the parameters of the hot and cold components on the increment for the waves propagating parallel to the magnetic field and at a small angle to it; it is shown that relativistic effects allow marked instability for the oblique Z mode only in a restricted energy range for the hot component. The relation between the extraordinary-wave increments is considered for longitudinal and transverse propagation. Analytic estimates are obtained for the increment and amplification coefficient for the Z mode in the case of perpendicular propagation. (Author abstract) 19 refs.

**079537 CONFINEMENT AND BALLOONING STABILITY AT THE BETA LIMIT.** Cross-field transport and ballooning stability in neutral heated ASDEX divertor tokamak plasma below and at the  $\beta$  limit are analysed by computer simulations. It is found that the discharge below the limit are ballooning stable and exhibit

H transport. No gradual reduction of confinement happens when beta approaches the limit ('hard'  $\beta$  limit). The degradation of energy confinement at the  $\beta$  limit is shown to be due to enhanced electron heat conduction. Resistive ballooning modes with high wavenumbers are found to be marginally stable or unstable in a radial zone where the electron heat diffusivity is enhanced by a factor of four. Broader zones correspond to stronger degradation of global energy confinement. The diffusion coefficient is raised much less than the electron heat diffusivity. Fast flattening of the current profile which keeps resistive ballooning modes close to marginal stability seems to occur. Such modes with high wavenumber generate small scale, fluctuating  $B_z$  fields which can cause magnetic braiding. It is shown that the confinement properties at the  $\beta$  limit are consistent with transport in stochastic magnetic fields. (Author abstract) 25 refs.

**079538 ASYMPTOTIC STABILITY BOUNDARIES OF BALLOONING MODES IN CIRCULAR TOKAMAKS.** The model ballooning mode equation of Connor, Hastie and Taylor for large-aspect-ratio circular tokamaks is analysed in the limit of large pressure gradient, and corresponding expressions for stability boundaries are derived. In particular, it is found that for fixed radial wavenumbers infinite sequences of unstable bands exist and that minimizing over the radial wavenumbers leads to asymptotic merging between the neighboring bands, which significantly modifies the second stability boundary compared with that for zero radial wavenumber. (Author abstract) 10 refs.

Chen, Liu (Princeton Univ, Princeton, NJ, USA); Bonedson, A.; Chance, M.S. *Nucl Fusion* v 27 n 11 Nov 1987 p 1918-1921.

**079539 HOT PARTICLE STABILIZATION OF BALLOONING MODES IN TOKAMAKS.** The concept of energetic particle stabilizing of ballooning modes in tokamak is extended by considering numerically generated finite aspect ratio equilibria and attempting to simultaneously stabilize all flux surfaces against ballooning modes by suitable choice of a hot particle anisotropic pressure. To achieve access to the second stability regime at as low as beta value as possible, tokamaks with circular cross-section and an aspect ratio of ten are considered. Global stabilization of ballooning modes is demonstrated, even though the drift reversal constraint requires careful tailoring of the anisotropic pressure profile. A prescription for determining the optimum anisotropic pressure profiles for any equilibrium is provided. (Author abstract) 28 refs.

**079541 EMISSION-BASED FEEDBACK SYSTEM FOR STABILIZING AN INDUCTIVELY COUPLED PLASMA.** An emission-controlled feedback system for stabilizing an ICP (Inductively Coupled Plasma) has been investigated. Unlike previous stabilization methods which monitor only the power being sent to the plasma, the present one uses an emission signal from either argon or an internal reference element as a stability indicator. Using a previously constructed power-modulation circuit for rf power control, the feedback network adjusts the plasma power to compensate for changes in the emission level of the reference element. It is shown to be particularly useful for reducing or eliminating the drift that occurs when the plasma is warming up. Results with several combinations

of argon, barium, calcium, iron, manganese, sodium, and strontium lines are presented. (Edited author abstract) 10 refs.

Marks, M.A. (Indiana Univ, Bloomington, IN, USA); Hietje, G.M. *Appl Spectrosc* v 42 n 2 Feb 1988 p 277-280.

**079542 TEMPORAL EVOLUTION OF REACTIVE AND RESISTIVE NONLINEAR INSTABILITIES.** A kinetic theory for nonlinear processes involving Langmuir waves, developed in an earlier paper, is extended through consideration of three aspects of the temporal evolution: (i) Following Falk & Tsytovich (1975), the dynamic equation for the rate of change of one amplitude at  $t$  is expressed as an integral over  $\tau$  of the product of two amplitudes at  $t-\tau$  and a kernel function  $f(\tau)$ ; two generalizations of Falk & Tsytovich's form  $f(\tau) \propto \tau$  that satisfy the requirement  $f(\infty)=0$  are identified. (ii) It is shown that the low-frequency or beat disturbance may be described in terms of fluctuations in the electron number density, and that its time evolution involves an operator that is essentially the inverse of  $f(t)$ . (iii) The transition from oscillatory evolution in the reactive or 'coherent-wave' version of the three-wave instability to the secular evolution of the resistive of 'random-phase' version is discussed qualitatively. (Author abstract) 8 refs.

**079543 STABILITY OF SHORT-AXIAL-WAVELENGTH INTERNAL KINK MODES OF AN ANISOTROPIC PLASMA.** The double adiabatic equations are used to study the stability of a cylindrical Z-pinch with respect to small axial wavelength, internal kink ( $m \geq 1$ ) modes. It is found that marginally (ideally) unstable, isotropic equilibria are stabilized. Also, constant-current-density equilibria can be stabilized for  $P_{\perp} > P_{\parallel}$  and large  $\beta_{z23}$ . (Author abstract) 9 refs.

Faghihi, M. (Royal Inst of Technology, Stockholm, Sweden); Scheffel, J. *J Plasma Phys* v 38 pt 3 Dec 1987 p 495-499.

**079544 FINITE LARMOR RADIUS EFFECTS ON THE STABILITY PROPERTIES OF INTERNAL MODES OF A Z-PINCH.** From the Vlasov-fluid model a set of approximate stability equations describing the stability of a cylindrically symmetric z-pinch is derived. The equations are derived in the limit of small gyroradius and include first order kinetic effects such as finite ion Larmor radius effects and resonant ion effects. Neglecting the resonant ion terms, we explicitly solve this set of equations for a constant current density profile leading to a dispersion relation. FLR effects are shown for the case of  $m = 1$  internal mode to be stabilizing and for large wavenumbers  $k$ , using a trial function approach, absolute stabilization is found. (Author abstract) 24 refs.

Akerstedt, Hans O. (Uppsala Univ, Uppsala, Sweden). *Phys Scr* v 37 n 1 Jan 1988 p 117-130.

**079545 REDUCTION OF RAYLEIGH-TAYLOR GROWTH DUE TO VISCOSITY EFFECTS.** The effect of viscosity on the growth reduction of Rayleigh-Taylor modes is studied. It is shown that short wavelength perturbations are strongly damped; however the growth of the most relevant modes in fusion pellets is nearly unaffected. (Author abstract) 4 refs.

Mulser, P. (Technische Hochschule Darmstadt, Darmstadt, West Ger). *Laser Part Beams* v 6 pt 1 Feb 1988 p 119-120.

**079546 EFFECTS OF BALLOONING INSTABILITY ON TOKAMAK CONFINEMENT.** Using the ballooning-mode transport model proposed by Connor, Taylor & Turner (1984), we derive the thermal conductivity induced by ideal ballooning instability and compare it to experimental observations from auxiliary-heated tokamaks. We show how this model can be improved by means of a finite-beta equilibrium and also apply it to obtain a confinement scaling law for high-beta, purely Ohmically heated tokamaks. Finally, we employ this transport mode

to find that tokamaks with supplemental stabilization, for example due to gyroradius, energetic particle or shaping effects, can self-consistently access the second stability regime at rather high heating power. (Author abstract) 18 refs.

**079547 STABILITY OF THE IDEAL  $m=1$  MODE IN A TOKAMAK.** The condition for stability of the ideal  $m=1$  mode in toroidal tokamak geometry is calculated for safety factor profiles which are flattened inside the  $q=1$  surface. It is shown that for such profiles the critical  $\beta_p$  for stability goes to zero as the safety factor on axis approaches unity. The critical  $\beta_p$  may therefore be small enough to explain sawtooth observations on JET. (Author abstract) 8 refs.

Nave, M.F.F. (JET Joint Undertaking, Abingdon, Engl); Wesson, J. *Nucl Fusion* v 28 n 2 Feb 1988 p 297-301.

**079548 INTERCHANGE STABILITY OF NON-CIRCULAR REVERSED FIELD PINCHES.** The interchange (Mercier) stability of toroidal reversed field pinch plasmas with non-circular cross-section has been evaluated numerically. Marginally stable pressure profiles and beta values have been produced. Most shapes, such as indented or vertically elongated, reduce the stability by making the net magnetic curvature of the poloidal field dominated plasmas yet worse than that of circular configurations. The stability of horizontally elongated plasmas is slightly enhanced compared with that of circular plasmas as a result of increased shear produced by toroidicity. This shear enhancement by toroidal shift of magnetic surfaces might be exploited in future, more comprehensive studies. (Author abstract) 7 refs.

Skinner, D.A. (Univ of Wisconsin, Madison, WI, USA); Prager, S.C.; Todd, A.M.M. *Nucl Fusion* v 28 n 2 Feb 1988 p 306-311.

**079549 EFFECTING THE CONDITION OF QUASISTATIONARY THERMONUCLEAR BURNING IN TOKAMAKS WITH A HIGH PLASMA DENSITY.** In the controlled thermonuclear fusion program, tokamaks with a strong magnetic field and high plasma density (Alcator, FT) are important; projects of such tokamaks of the following generations - IGNITOR-A, BCX, and T-14 - are considered. The main advantages of these tokamaks are that the energy losses caused by the heat conduction of the electrons decrease in inverse proportion to the plasma density. Obviously, a high plasma density implies operation on the left (low-temperature) branch of the ignition curve where there is the problem of the stability of thermonuclear burning. The authors analyze in the present work this stability and make numerical one-dimensional calculations of the plasma parameter changes for both unstabilized burning and for stabilized burning with feedback obtained by introducing a timewise modulated additional heating. 8 refs.

**079551 STABILIZATION OF THE TARA TANDEM MIRROR PLASMA BY MHD ANCHORS.** The effectiveness of a warm ion and hot electron population in the Tara outboard minimum-B anchors in stabilizing MHD flute-like modes in the central cell and axioids is assessed. With a combination of ECH and ICRF heating in the anchors,  $\beta_{he} > 15\%$  and  $\beta_i$  approximately 0.5% have been obtained. The ICRF component has a generally stabilizing effect on global MHD activity, but the stabilization is not linear in ion beta. Pinhole camera pictures indicate that the hot electron density profile is radially peaked. The resulting creation of a deeper magnetic well for the warm ions was expected to enhance the MHD stabilizing properties of the anchor. However, the addition of hot electron beta to an ICRF heated anchor plasma was observed to have no beneficial effect on MHD stability. (Author abstract). 23 Refs.

**079552 KINETIC THEORY OF THE  $m=1$  KINK INSTABILITY IN Z-PINCHES.** The kinetic theory of the  $m=1$  kink instability of a Z-pinch with Bennett profile is presented. The dominant particle trajectories in the equilibrium field are the large excursion betatron orbits. To deal with these orbits, an integral formulation of the stability analysis is adopted. In this case, the dispersion relation is expressed as the determinant of a matrix. In the limit where the electrostatic perturbation is neglected, the eigenmodes are computed numerically from this dispersion relation. Two methods are used to obtain the growth rates, and the computed values agree very well. The Landau damping of the mode is found to be strong enough to stabilize the mode at shorter wavelengths. This may explain the stability of the kink mode in some experiments. (Author abstract). 23 Refs.

**079554 TOROIDAL INTERNAL KINK STABILITY IN TOKAMAKS WITH ULTRA FLAT  $q$  PROFILES.** Linear stability properties of the ideal internal kink mode in toroidal geometry are calculated for equilibria in which the  $q(r)$  profile is very flat and  $q \approx 1$  in the core region of the plasma. Marginal stability criteria and growth rates are calculated analytically in the large aspect ratio limit and compared with numerical results from the FAR code. The theory is developed for  $m=n=1$  modes and for higher  $m(=n)$  modes. The temperature perturbation due to adiabatic expansion in the linear phase of the  $1/1$  mode is calculated and compared with experimental data, showing that the predictions from ideal MHD theory cannot account for the observed temperature increase on JET. Comparison with collisionless theory suggests that the observed temperature increases can be accounted for by compression of the trapped particles. (Author abstract). 17 Refs.

**079555 OBSERVATION OF TILT STABILITY OF FIELD REVERSED CONFIGURATIONS AT LARGE  $s$ .** Experiments were carried out on the TRX field reversed theta pinch in which  $s$ , the number of ion gyroradii between the magnetic null and the separatrix of a field reversed configuration, was increased significantly compared with previous experiments where  $s \leq 2$ . Sustained values of  $s > 4$  were obtained in hydrogen discharges with configuration lifetimes as long as twenty tilt growth times, where the calculated growth rate reduction due to ion kinetic effects has been accounted for. (Author abstract). 18 Refs.

**079556 LARGE  $m=3n=1$  LOCKED MODE IN JT-60 AND ITS STABILIZATION.** An  $m=3/n=1$  locked mode has been observed in JT-60 at safety factors slightly below three during the current ramp-up phase of high plasma current discharges. The locked mode grows suddenly and there is no Mirnov oscillation just before the onset of this mode. The maximum plasma current of Ohmic discharges is restricted to approximately 2.4-2.45 MA by disruptions, which are preceded by a large  $m=3/n=1$  locked mode. The locked mode is stabilized by high power neutral beam injection. The stabilizing effect depends on neutral beam heating power, plasma density, plasma current ramp-up rate and divertor/limiter configuration. (Author abstract). 8 Refs.

**079557 OBSERVATION OF POTENTIAL RELAXATION INSTABILITY IN A BOUNDED DISCHARGE PLASMA.** A potential relaxation instability (PRI), which causes a periodic motion of a potential jump and plasma expansion accompanying a high-density fluctuation level ( $\approx 60\%$ ), is observed in a bounded discharge plasma. The instability is found to create a high electron-drift velocity and a spatial growth of density and potential fluctuations, and to accelerate a test wave. An additional injection of a plasma into the boundary suppresses the instability. At the same time, the fluctuation decreases ( $< 5\%$ ) and the frequency difference of the wave spectrum between  $n$ th and  $(n-1)$ th ( $n$  is an integer) higher harmonics decreases as the frequency increases. However, when the potential relaxation instability is excited, this frequency difference remains constant. 22 refs.

**079558 COMPRESSIONAL EFFECTS ON DRIFT-RESISTIVE INSTABILITIES IN GENERAL TOROIDAL PLASMA.** The drift-resistive modes in general toroidal geometry are studied analytically and numerically. The effects of ion acoustic couplings, ion polarization drift, and perpendicular resistivity are included. These effects can completely stabilize the drift-resistive modes. The perpendicular resistivity is effective mainly in stabilizing the drift interchange modes, while the ion-acoustic couplings are the dominant mechanism for the stabilization or the drift-tearing modes. From the ion polarization drift effects of the perpendicular compression, the critical value of magnetic  $\Delta_c$  saturates for a moderate diamagnetic drift frequency region. The favorable average curvature is a stabilizing factor for the drift-tearing modes with  $\Delta' < \Delta_c$ , but an instability from unfavorable curvature exists in the semicollisional region, even for  $\Delta' < 0$ . 19 refs.

**079559 AXIAL FEEDBACK STABILIZATION OF FLUTE MODES FOR MIRROR MACHINES.** A novel

scheme of feedback stabilization of the  $m=1$  flute mode for axisymmetric mirror machines is proposed that has potential for reactor extrapolation. A three-region plasma model is analyzed, consisting of a hot core surrounded by a warm transition annulus, which in turn is surrounded by a warm halo annulus that is in contact with segmented annular feedback plates at the two end walls. For plasma parameters characteristic of the TMX-U and MFTF-B devices at the Lawrence Livermore National Laboratory and the MMX device at the University of California, Berkeley, the required feedback power is calculated. The results show that stability can be achieved in the MMX and TMX-U devices with a modest feedback gain and power. The power requirement for the near-reactor conditions of MFTF-B is more severe, but can be reduced by a modified choice of plasma parameters. 23 refs.

## Surfaces

**079560 COMPUTER SIMULATION OF THE DYNAMICS OF PLASMA-SURFACE INTERACTIONS IN VACUUM ARC CATHODE SPOTS.** The theory of the vacuum arc cathode spot is reviewed, covering the E-diagram method as well as advanced nonstationary cathode spot models. The cathode spot model used for the computer simulation is described in detail. The simulation results show that within the model assumptions, a steady-state self-sustaining cathode spot does not exist. On the one hand, plasma-wall interactions with steady-state thermal equilibrium exist below the balance conditions of mass and energy, while on the other hand, real cathode spots that meet the requirements of both mass and energy balance never show thermal equilibrium but are characterized by thermal runaway. Therefore, instability is an inherent feature of cathode spots. Computational values and representative experimental results for cathode spot characteristics show a rather good agreement, further supporting the validity of the model. 36 refs.

## Switching

**079561 PLASMA OPENING SWITCH DEVELOPMENT FOR THE PARTICLE BEAM FUSION ACCELERATOR II (PBFA II).** Plasma opening switch (POS) experiments have been conducted on Sandia National Laboratories' Particle Beam Fusion Accelerator II (PBFA II) (12 MV, 100 TW, 50 ns), on the Supermite accelerator (2 MV, 2 TW, 50 ns) and on the US Naval Research Laboratory's Gamble II accelerator (1.8 MV, 1.6 TW, 70 ns). In the Supermite experiments, the POS conducted currents of up to 1 MA before opening in less than 10 ns into an electron beam load. These experiments achieved significant voltage gain relative to the voltage across a matched load. In experiments on Gamble II, power gains of up to 1.7 were achieved using a POS in a strongly coaxial geometry with a large magnetic field at the cathode. The POS system on PBFA II is unique because of its size and voltage. This POS system is designed to conduct over 6 MA before opening. Experiments are presented in which it has conducted currents of 4-5 MA for over 50 ns. 17 refs.

**079562 LOW-JITTER LASER-TRIGGERED VACUUM SWITCH USING A COMPOSITE TARGET.** A laser-triggered high-voltage vacuum switch with a composite KCl/Ti target pellet is described. The switch triggers reliably for 532-nm laser input energies of 20  $\mu$ J corresponding to a peak irradiance of 1 MW/cm<sup>2</sup>. Jitter times of less than  $\pm 15$  ns and delay times of less than 100 ns are observed. Several experiments were performed to explore the operation of the switch. It was found that the amount energy needed to trigger the switch and the jitter time was strongly dependent on the position of the pellet relative to the cathode. It is noted that the mechanism responsible for the operation of the switch is not completely understood. 12 refs.

## Temperature Measurement

**079563 TAKING INTO ACCOUNT THE RADIATION FROM THE CHANNEL WALLS IN OPTICAL MEASUREMENT OF THE TEMPERATURE OF SOLID-FUEL COMBUSTION-PRODUCT PLASMA.** A model of the method of spectral-line reversal (emission-absorption method) for measuring the temperature of a plasma with a condensed phase taking into account the scattering of radiation by the channel walls is studied. An approximate analytical solution is obtained for the problem of radiation transfer for a layer of absorbing and scattering medium, bounded by emitting walls. It is shown that the corresponding correction reduces the measured temperature and depends strongly on the geometry of the system. (Author abstract) 8 refs.

**079564 COMPARATIVE STUDY OF ROTATIONAL TEMPERATURES IN A MICROWAVE PLASMA: OH RADICAL VERSUS  $N_2^+$ .** A rotational temperature comparative study of OH radical vs.  $N_2^+$  was carried out on a low-power helium microwave-induced plasma. Under the prevailing conditions,  $N_2^+$  was found to provide twice as many usable lines for temperature measurement than did hydroxyl radical. For the particular torch design used, both species exhibited slightly increasing rotational temperatures at low flow rates. At fixed conditions, OH consistently indicated higher rotational temperatures than those of the molecular nitrogen ion. Positional studies revealed a slightly increasing temperature near the center of the plasma. (Edited author abstract) 18 refs.

**079565 ESTABLISHMENT OF DEBYE POTENTIAL IN A SLIGHTLY NONIDEAL PLASMA.** A multiparticle dynamic method is used to investigate the dependence of the time correlation functions of micropotential on the parameters of a plasma. It is shown the Debye potential is the result of averaging in an interval of time which exceeds the time for covering the mean interparticle distance. In this case the concept of the Debye potential retains its sense even if on the average less than a single particle is located in the Debye sphere. (Author abstract) 3 refs.

**079566 ELECTRON CYCLOTRON ABSORPTION FOR OBLIQUE PROPAGATION IN LOSS-CONE PLASMAS.** The components of the dielectric tensor for a plasma described by a relativistic loss-cone electron distribution are written in a simple way, which takes full account of relativistic effects, harmonics and Larmor

radius, for perpendicular and oblique propagation. For sufficiently oblique propagation and temperatures in the thermonuclear range, a still simpler form of the dielectric tensor is derived. The role of the wave parameters in the absorption is discussed, and some comments are made about the weakly relativistic and non-relativistic approaches. A numerical example is given for both the extraordinary and ordinary modes. (Author abstract). 28 Refs.

**079567 ON THE EFFECT OF LANDAU DAMPING IN A RELATIVISTIC ELECTRON ACOUSTIC PLASMA.** We have considered the effect of damping generated due to streaming electrons in a relativistic electron plasma. It is observed that due to the relativistic effect the amplitude of the soliton gets smaller and it becomes more widened. But for a high-temperature electron plasma, the effect is not considerable. The KdV equation with the damping term is solved via the Bogoliubov-Krylov perturbation theory, whence the amplitude and width of the soliton are expressed in terms of the parameters of the plasma. Lastly we discuss how higher order effects can be incorporated. (Author abstract). 17 Refs.

## Thin Films

**079571 CORRELATIONS ENTRE LA NATURE DU PLASMA DE DECHARGE ET LES CARACTERISTIQUES METALLURGQUES DES DEPOTS DE COMPOSES METALLIQUES REFRACTAIRES DANS LES SYSTEMES DE DEPOTS IONIQUES.** [Correlations within the Nature of Discharge Plasma and Metallurgical Characteristics of Deposition of Refractory Metallic Depositions in the Systems of Ionic Depositions]. In order to obtain a good correlation between the nature of the plasma present in the VPD and ion plating systems and metallurgical properties of thin films, the problem of the reproducibility of the measurements has been studied. For the high deposition rate apparatus (more than 1 gram per hour), one can observe a very important and fast evolution of the physical nature of the system with running time. This evolution is connected to the variations of the physical parameters of the deposition system which can be connected to the spectroscopic observations and to the analysis of the coating. For example, the evolution of the deposition rate can be characterized by the running parameters with the spectroscopic measurement of the metallic specimen density. (Edited author abstract) 7 refs. **079572 TRANSPORT ANALYSIS OF INJECTED IMPURITIES IN CURRENTLESS HELIOTRON E PLASMAS.** Impurity transport in currentless Heliotron E plasmas is examined. The main aim of the experiment is to clarify the density dependence of impurity transport both in electron cyclotron heated (ECH) and neutral beam injected (NBI) plasmas. In experiments with a stationary electron density, the confinement time of impurities is determined as a function of the line averaged electron density. The inherent difference between ECH and NBI plasmas, observed in an earlier measurement, seems to have been masked by the operating conditions. From a direct comparison between NBI plasmas and simultaneous ECH and NBI heated plasmas of the same density, a pumping-out effect of impurities by the ECH pulse is established. (Edited author abstract) 25 refs.

**079573 GLOBAL PARTICLE CONFINEMENT IN THE TEXAS EXPERIMENTAL TOKAMAK.** Particle transport in an ohmically heated tokamak plasma was investigated in the Texas Experimental Tokamak (TEXT). Spectroscopic measurements of the electron source were used with electron density measurements to derive particle confinement times from the continuity equation. Scalings were developed for particle confinement time with electron density, plasma current, toroidal field, and plasma positioning. Simultaneous measurement of electrostatic fluctuations with Langmuir probes may suggest a correlation between edge particle transport in TEXT and electrostatic turbulence. In addition, two major features of transport were isolated. (Edited author abstract) 26 refs.

**079575 NEOCLASSICAL RESONANT PLATEAU TRANSPORT CALCULATION IN AN EFFECTIVELY AXISYMMETRIZED TANDEM MIRROR WITH FINITE ENDPLATE RESISTANCE.** Calculations are made for neoclassical resonant plateau transport in the geometry of the effectively axisymmetrized tandem mirror GAMMA 10 magnetic field, which has minimum B inboard anchors inside the axisymmetric plug/barrier mirror cells. Azimuthal drifts in the local, non-axisymmetric regions are included. The radial potential profile is determined by solving the charge neutrality equation self-consistently. A finite resistance connecting the end plate to the machine ground provides appropriate boundary conditions on the radial electrostatic potential distribution so that it can be determined uniquely. The calculation is consistent with experimental results of GAMMA 10. (Author abstract) 23 refs.

**079576 MODELLING OF PELLET INJECTION EXPERIMENTS WITH ONSAGER-SYMMETRIC TRANSPORT RELATIONS.** The formalism of non-equilibrium thermodynamics is applied to the problem of radial transport in tokamak plasmas. Phenomenological relations between generalized forces and fluxes, consistent with the empirical Alcator scaling, are suggested. A simple 1-D transport model incorporating these relations is shown to reproduce the salient features of recent pellet injection experiments on Alcator-C; a drop in the central temperature preceding pellet penetration, rapid ( $< 1$  ms) peaking of the density profile, a marked rise in the energy confinement time immediately following injection and persistence of the state of high confinement and peaked density for a time longer than the initial confinement time. The same model reproduces a saturation of Alcator scaling when the density profile becomes that, as is observed in high density, edge fuelled Alcator-C discharges. (Author abstract) 17 refs.

**079577 DETERMINATION OF AMBIPOLAR RADIAL TRANSPORT FROM THE PARTICLE BALANCE IN THE TMX-U TANDEM MIRROR.** Ambipolar radial transport (equal ion and electron flux) is not directly measured in tandem mirror experiments because the particle flow does not produce a net electrical current. The first absolute measurements of the ionization source in the tandem mirror experiment upgrade (TMX-U) plasma have been obtained. These have permitted the determination of magnitude of ambipolar radial transport from the particle balance. Furthermore, comparisons of the source measurements with a Monte Carlo neutral transport code have shown reasonable agreement. Measurements of the particle balance under several operating conditions are presented. For some of these cases, the ambipolar radial transport is smaller than the other measured losses. (Author abstract) 26 refs.

Allen, S.L. (Lawrence Livermore Natl Lab, Livermore, CA, USA); Correll, D.L.; Hill, D.N.; Kaiser, T.B.; Heifetz, D.B. *Nucl Fusion* v 27 n 12 Dec 1987 p 2139-2152.

**079578 KINETIC AND TRANSPORT THEORY FOR A NON-NEUTRAL PLASMA TAKING ACCOUNT OF STRONG GYRATION AND NON-UNIFORMITIES ON THE COLLISIONAL SCALE.** From the BBGKY equations for a pure electron plasma a derivation is made of a collision integral that includes the combined effects of particle gyration in a strong magnetic field and non-uniformities of both the distribution function and the self-consistent electric field on the collisional scale. A series expansion of the collision integral through the distribution function and the electric field on the collisional scale is carried out to third order in derivatives of the distribution function and to second order in derivatives of the electric field. For the strong-magnetic-field case when collision-term contributions to only first order in  $1/B$  are included, a particle flux transverse to the magnetic field proportional to  $1/B^2$  is derived. The importance of long-range collective collisions in this process is shown. The result is in contrast with the classical  $1/B^4$  proportionality, and is in accordance with earlier studies. (Author abstract) 9 refs.

Oien, Alf H. (Univ of Bergen, Norw.). *J Plasma Phys* v 38 pt 3 Dec 1987 p 351-371.

**079579 TRANSPORT SIMULATION OF A FIELD-REVERSED CONFIGURATION PLASMA.** A numerical simulation of the evolution of a field-reversed configuration (FRC) plasma is described. The calculation proceeds by alternating between a two-dimensional axisymmetric equilibrium calculation and a one-dimensional transport calculation. The equilibrium calculation uses flux-surface coordinates and finite elements. The transport calculation consists of the simultaneous solution of three one-dimensional equations for the differential ion density, electron entropy, and ion entropy. The transport calculation includes classical transport processes, loss on open field lines, radiation cooling due to impurities, and lower hybrid drift anomalous transport. Examples of FRC simulations are presented. (Author abstract) 25 refs.

**079582 STANDARD TEST CASES FOR THE BALDUR TRANSPORT CODE.** Fourteen test cases have been developed to benchmark the BALDUR code. This report documents these test cases and results of simulations

run with BALDUR version BALDP47M (March 1986). Five of the test cases are based on analytical solutions of the diffusion equations. The analytical test cases check the accuracy of the numerical simulation of particle diffusion as well as energy convection and conduction. Additional benchmark cases were developed to exercise the four impurity capabilities of BALDUR, especially the neutral impurity influx model; and the semiempirical formulation of transport coefficients, and to document BALDUR's simulation of specific tokamaks. Most of the cases were verified by comparison with the test cases run with version BALDP17M. 3 refs.

**079584 SOME REMARKS ON SPONTANEOUS MAGNETIC FIELD GENERATION AND THE NON-LINEAR DYNAMICS OF A LANGMUIR PLASMA.** It is shown that, in the hydrodynamic approximation, the spontaneous generated magnetic field does not act directly on the development of Langmuir plasma turbulence. It is shown that besides the magneto-modulational effects, it is necessary to take into account the purely relativistic effect, i.e. the dependence of the electron mass on velocity. In most cases the contribution of this relativistic effect prevails over the spontaneous magnetic field contribution to the development of the modulational instability of HF waves. (Author abstract) 15 refs.

**079585 CHARACTERIZATION OF TOKAMAK EDGE TURBULENCE BY FAR-INFRARED LASER SCATTERING AND LANGMUIR PROBES.** The spectra, magnitude and spatial distribution of low-frequency density fluctuation have been measured by two independent experimental methods in the edge plasma of the TEXT tokamak. Good agreement between far-infrared laser scattering and Langmuir probe measurements has been achieved and the strengths of each technique are evaluated. Langmuir probes are used to directly determine the particle flux induced by edge fluctuations and collective Thomson scattering permits an extension of these observations to the plasma interior. Results are presented for typical discharge conditions in a tokamak. (Edited author abstract) 26 refs.

Ritz, C.P. (Univ of Texas at Austin, Austin, TX, USA); Brower, D.L.; Rhodes, T.L.; Bengtson, R.D.; Levinson, S.J.; Luhmann, N.C. Jr.; Peebles, W.A.; Powers, E.J. *Nucl Fusion* v 27 n 7 Jul 1987 p 1125-1134.

**079586 TOWARDS A THEORY OF INSTABILITY OF A TURBULENT PLASMA.** In conditions of the new hydrodynamics which qualitatively differ from the normal and are characterized by paired collisions, it follows that the anomalous transfer and anomalous redistribution of heat leads to a new hydrodynamic instability of the

potential type with which there is oscillation of the perturbations at a frequency close to the frequency of ionic sound. This report shows the possibility of another hydrodynamic instability which is responsible for the rise in perturbations at frequencies lower than the ionic-sonic frequency. Conditions are identified at which the state of the plasma is unstable with respect to the oscillation of such perturbations. 4 refs.

Bychenkov, V.Yu.; Silin, V.P. *Sov Phys Lebedev Inst Rep* n 3 1987 p 46-50.

**079587 SPECTRUM, SPATIAL DISTRIBUTION AND SCALING OF MICROTURBULENCE IN THE TEXT TOKAMAK.** Strong asymmetries in the spectrum and magnitude of low frequency ( $\omega \ll \omega_{ci}$ ) density fluctuations in the Texas Experimental Tokamak (TEXT) are described. Microturbulence is investigated under a variety of plasma parameters and a comparison with mixing length theory is made. Broadband fluctuations are observed throughout the plasma cross-section, but they peak at the limiter and possess a strong up-down asymmetry which inverts with reversal of plasma current direction. The spatial distribution of these fluctuations can be dramatically altered by the introduction of a point limiter. Inside the magnetic axis, a large-magnitude quasi-coherent fluctuation is seen to dominate the ubiquitous broadband microturbulence. This type of fluctuation peaks on the midplane. For high density discharges, a distinct ion mode (density fluctuations propagating in the ion diamagnetic drift direction) is observed in the microturbulence spectra. Onset of the ion feature occurs at plasma densities where a clear saturation is evident in the global energy confinement time. (Edited author abstract) 40 refs.

**079588 TURBULENT FLUCTUATIONS AND CONFINEMENT IN JET.** High frequency fluctuations are observed in JET by edge magnetic probes and arrays of visible radiation detectors even in the absence of Mirnov activity (typical frequency: approximately 1 kHz); cross-correlation techniques are applied in order to study the broadband activity. Magnetic fluctuations ( $b \approx 2$ ) in the range 1 to 20 kHz are strongly correlated along a direction parallel to the edge magnetic field lines; above approximately 10 kHz, a substantial fraction of these fluctuations (30-60%) have low wavenumbers ( $m \leq 5$ ,  $n \approx 1$ ). Fluctuations in visible radiation coming from the edge are detected by soft x-ray diodes (without absorptive foil) up to approximately kHz: correlation analysis indicates the presence of rather high  $m$  numbers ( $m$  approximately 10-100) with a correlation time of  $\tau_c$  approximately 100  $\mu$ s. This type of activity is also seen by the magnetic probes and a good correlation between the two diagnostics is observed. (Author abstract) 29 refs.

**079589 MEASUREMENTS OF EDGE TURBULENCE WITH LANGMUIR PROBES IN CURRENTLESS HELIOTRON E PLASMAS.** A study of microscopic fluctuations of density  $n$  and  $\phi$  in the scrape-off layer has been performed. The frequency spectra of  $n$  and  $\phi$  show a strongly turbulent character, as observed in many tokamaks. The fluctuation levels of  $n$  and  $\phi$  are consistent with predictions based on non-linear collisional drift wave models. The line average density and heating power dependences of  $n$  and  $\phi$  are studied in two types of currentless plasma, namely electron cyclotron resonance heating plasmas and neutral beam injection heating plasmas. Their parametric dependences are compared with the trends of the energy confinement time. Finite beta effects on  $\phi$  and  $n$  are also discussed. (Author abstract) 39 refs.

**079591 XIITH INTERNATIONAL SYMPOSIUM ON DISCHARGES AND ELECTRICAL INSULATION IN VACUUM.** This issue contains 21 conference papers dealing with various aspects of vacuum discharge plasmas. In the most common form of vacuum discharge, namely, the vacuum arc, the plasma consists of evaporated and ionized electrode material, with plasma generation typically not uniform over all boundary surfaces, but tending to concentrate in a characteristic manner at selected surfaces, and defining a variety of arc modes, like cathode and anode spot arcs. Various properties of plasmas and the utilization of vacuum discharges in a wide spectrum of technological applications are considered, including switching, thin film deposition, ion and plasma sources, metal refining, X-ray generation, isotope separation and spacecraft propulsion. Plasma transport in vacuum arcs and high current vacuum diodes, power frequency vacuum interrupters, nanosecond-speed pulses power devices, and critical phenomena are also discussed. All of the papers are abstracted and indexed separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10793 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**079592 HIGH-POWER (3-MW) LONG-PULSE (3-s) RADIO-FREQUENCY SYSTEM FOR ION CYCLOTRON RESONANCE HEATING EXPERIMENTS ON TEXTOR.** A megajoule ion cyclotron resonance heating (ICRH) experiment was installed on the Torus Experiment for Technology-Oriented Research (TEXTOR) tokamak. The system consists of two independent power lines each designed to generate and launch 1.5 Mw of radio-frequency (rf) power into the machine during a 3-s period in the 25- to 29-MHz frequency range. Each power line consists of the following items: (a) a 1.5-Mw transmitter, (b) a transmission line system, including a two-stub tuner, made of pressurized 155.6-mm (6.125-in.) and 228.6-mm (9-in.) rigid coaxial line components, and (c) an interface linking the transmission line to the antenna of the shielded stripline type placed along the tokamak's hot liner. Details of the line and antenna diagnostics and data acquisition system together with the subsequent impedance characteristic calculations are given. The rf radiation shielding for the ICRH experiment is explained. The control of the rf setup as a TEXTOR subsystem and the generator pulse control and operation modes are outlined. The antenna loading and power limitation in the presence of plasma and the conditioning procedure are discussed. Finally, the new rf system compatible with the toroidal pump limiter Advanced Limiter Test-II is presented. (Author abstract) 27 refs.

haas, W.; Stickelmann, C.; Cosler, A. *Fusion Technol* v 12 n 3 Nov 1987 p 449-475.

**079593 LIGHT PRESSURE INDUCED MODULATIONS IN A PLASMA.** The modulation of electron densities in a plasma introduced by a standing electromagnetic wave is studied theoretically. The transmissivity of a probe monochromatic wave through the plasma gives, according to the theoretical analysis, 'bands' of stable and unstable regions of frequencies, with properties which are related to Mathieu's or Hill's type equations. (Author abstract) 16 refs.

**079594 PONDEROMOTIVE FORCE NEAR CYCLOTRON RESONANCE.** The ponderomotive force in a magnetized plasma is derived by carrying out the renormalization of wave-particle interactions based on the Vlasov equation. A significant feature of the result is non-singular behaviour at resonance even in the case of perpendicular propagation. This is shown to be related to the onset of the diffusive motion of particles due to the orbit instability near resonance, where the ponderomotive force is eventually small. (Author abstract) 7 refs.

**079595 NON-RELATIVISTIC THERMAL EFFECTS ON PARALLEL-PROPAGATING ION CYCLOTRON WAVES.** We investigate strictly non-relativistic thermal effects on the dispersion of left-handed (LH) ion cyclotron waves (ICW's) with real frequency and complex wave vector, propagating parallel to a uniform ambient magnetic field. Changes to the topology of the cold-plasma dispersion relations in the vicinity of the ion gyrofrequencies are studied in plasmas consisting predominantly of protons with a small admixture of a heavy ion. This work is relevant to theories of ion heating and acceleration in multi-ion plasmas as are found in the solar wind, in solar and stellar flares, and in the Earth's magnetosphere. In particular, strongly species-dependent heating and acceleration can arise from wave-particle interactions between the various ionic species, and ICW's at frequencies near the respective ion gyrofrequencies. These interactions depend critically on the wave dispersion. (Edited author abstract) 17 refs.

**079596 NUMERICAL ANALYSIS OF ALFVEN CURRENT DRIVE AND PLASMA IMPEDANCE DYNAMICS TAKING INTO ACCOUNT TRANSPORT PROCESSES.** Absorption of radiofrequency (RF) waves within the Alfvén range of frequencies ( $\Omega \leq \omega_{H_i}$ ) and current drive generation by Alfvén waves are studied in a cylindrical plasma column, with particle, heat and magnetic field diffusion processes taken into account. To this end a 1-D numerical code describing RF field propagation, absorption and current drive processes has been developed, with a self-consistent evolution of the plasma parameters. The code structure includes electrodynamic and transport equations that are solved alternately with a 1 ms time order step. Two different regimes have been found in the model, depending on the direction of the RF field rotation. (Edited author abstract) 18 refs.

**079597 CONVECTIVE INSTABILITY OF ALFVEN ION CYCLOTRON WAVES IN FINITE BETA TURBULENT PLASMAS WITH ANISOTROPIC IONS.** The full dispersion equation for linear Alfvén ion cyclotron waves propagating along a uniform magnetic field in a finite beta turbulent plasma with anisotropic ions is

solved numerically for complex wavenumbers. The influence of a stationary, small scale Langmuir background turbulence on the real part of the wavenumber and the spatial growth rate of the Alfvén ion cyclotron instability is investigated. It is found that the presence of turbulence makes the spatial growth substantial before the wave comes out of a finite length laboratory plasma. The applicability of the results to a tandem mirror machine is discussed. (Author abstract) 11 refs.

**079598 EXACT AND APPROXIMATE SOLUTIONS TO THE FINITE TEMPERATURE WAVE EQUATION IN A ONE-DIMENSIONAL PERPENDICULARLY STRATIFIED PLASMA.** The sixth order wave equation which results from a finite temperature expansion of the Vlasov equation is solved globally in the ion cyclotron range of frequencies. A perpendicularly stratified, one-dimensional slab plasma is assumed. The diamagnetic drift and the associated anisotropy are included in the unperturbed distribution function to ensure a self-adjoint system. All  $x$ -dependence in the plasma pressure and magnetic field is retained along with the electric field parallel to  $B$ . Thus, Landau damping of the ion Bernstein wave is included self-consistently. (Edited author abstract) 26 refs.

**079599 STABILIZATION OF SAWTEETH BY LOWER HYBRID WAVES IN THE ALCATOR C TOKAMAK.** Sawteeth have been suppressed by lower hybrid current drive in high density Alcator C plasmas. The experiments discussed in this paper demonstrate the possibility of decoupling temperature and partially RF driven current profiles in subtle ways. Further studies along these lines may help us to find new and perhaps more efficient ways to stabilize MHD modes in a toroidal plasma (it is estimated that in the present experiments  $I_{RF}/I_{Total} = 0.2$  when stabilization is achieved). Furthermore, these studies help to improve our understanding of the MHD stability of toroidal plasma systems, as well as elucidate the limitations of partially toroidal MHD models compared with fully toroidal MHD codes, which have gained favor in recent studies. 17 refs.

**079600 ION CYCLOTRON WAVE EFFECTS ON THE ION VELOCITY DISTRIBUTION IN A TANDEM MIRROR.** Experiments have been conducted in the end cells of a tandem mirror to determine the effect of ion cyclotron resonance heating (ICRH) on the ion pitch angle and velocity distribution. An ICRH power of  $2.4 \text{ W} \cdot \text{cm}^{-3}$  was measured to have both a directed and a diffusive velocity space effect on the mirror trapped plasma ions, which have densities of  $(4-6) \times 10^{12} \text{ cm}^{-3}$  and average perpendicular energies of 600-1000 eV. On low energy streaming ions, the ICRH has a directed pitch angle effects which causes a dominant number of the eventually trapped ions to reflect or to mirror near the resonant magnetic field and to generate a sloshing ion like velocity distribution. However, a sloshing ion like axial density profile was not measured. These observations are discussed in the context of RF kick-per-pass and quasi-linear theory. (Edited author abstract) 28 refs.

**079603 THREE WAVE SOLITON INTERACTIONS IN WARM MAGNETIZED PLASMAS.** In the nonlinear interaction between three waves described by coupled-mode equations, the waves interact by continuously transferring energy between themselves, resulting in bounded periodic solutions for the individual wave envelopes. However, when three waves interact with pulse widths sufficiently narrow so that their pulse durations are commensurate with the characteristic time for the interaction, steady state pulse profiles result and the three wave envelopes propagate as solitons. This latter aspect of nonlinear wave propagation is studied. Starting with the couple-mode equations, these soliton solutions are derived and the theory is applied to the nonlinear interactions between upper- and lower-hybrid waves and electron and ion Bernstein modes propagating in a warm magnetized plasma. Half widths for the solitons are calculated together with estimates of their speed of propagation which are computed for some typical laboratory plasmas. (Author abstract) 20 refs.

**079604 NONLINEAR ION-ACOUSTIC WAVES IN MULTICOMPONENT PLASMAS.** By applying the reductive perturbation technique to the basic system of equations governing plasma dynamics, a modified Korteweg-de Vries (KdV) equation is derived. The inclusion of nonisothermality, together with its reduction to a small magnitude, yields various interesting characteristics relating to the existence of solitons in multicomponent plasmas that include several ionic species and multiple nonisothermal electrons. The mathematical development shows that a closed relation among the solitons existing in the various plasma arises due to the different magnitude of nonisothermality. (Author abstract) 16 refs.

**079605 LOWER HYBRID EXPERIMENTS ON PLT USING GRILLS WITH VARIOUS  $n_{\perp}$  SPECTRAL WIDTHS.** Coupling structures for lower hybrid current drive experiments have, until now, been smaller than a free space wavelength and have had a correspondingly broad wavenumber spectrum. The paper reports the results of experiments on the PLT tokamak using a 16-waveguide grill (2.2 wavelengths) which produces a very narrow  $n_{\perp} = k_{\perp} c/\omega$  spectrum. Experimental results from the 16-waveguide grill are compared with results from three other PLT grills with less sharply defined  $n_{\perp}$  spectra. The experimental results are consistent with the first-pass damping of a large fraction of the launched spectrum. (Edited author abstract) 47 refs.

**079606 ION RADIAL TRANSPORT INDUCED BY ICRF WAVES IN TOKAMAKS.** The wave induced

fluxes of energetic trapped ions during ICRF heating of tokamak plasmas are calculated by using quasi-linear equations. A simple single particle model of this transport mechanism is also given. Both a convective flux proportional to  $k_{\perp} |E_{\perp}|^2$  and a diffusive flux proportional to  $k_{\perp}^2 |E_{\perp}|^2$  are found. Here,  $k_{\perp}$  is the toroidal wavenumber and  $E_{\perp}$  is the left hand polarized wave field. The convective flux may become significant for large  $k_{\perp}$  if the wave spectrum is asymmetric in  $k_{\perp}$ . But for  $k_{\perp} \rho \ll 1$ , a conditioned satisfied in most previous and planned experiments, radial transport driven directly by the ICRF wave is unimportant. (Author abstract) 15 refs.

Chen, Liu (EURATOM, Lausanne, Switz); Hammett, G.W.; Vacklavik, J. *Nucl Fusion* v 28 n 3 Mar 1988 p 389-398.

**079607 FULL-WAVE CALCULATIONS OF THE O-X MODE CONVERSION PROCESS.** A two-point boundary-value problem has been formulated that describes the conversion between ordinary (O) and extraordinary (X) wave modes in a cold inhomogeneous plasma. Numerical solutions to this problem have been obtained for various values of the WKB parameter  $k_0 L$ , where  $k_0$  is the vacuum wavenumber and  $L$  the density-gradient scale length. The results are compared with three different theoretical expressions for the O-X mode conversion efficiency derived by others in the WKB limit of  $k_0 L \ll 1$ . Most of the results presented in this paper are obtained for a collisionless plasma with finite density near the plasma cut-off density. However, some examples are also given of wave propagation from vacuum. In these examples, collision effects are added to the equations in order to remove the singularity otherwise present at the position of the upper hybrid resonance layer. (Author abstract) 20 refs.

**079608 DECAY OF A WHISTLER WAVE IN A HOT-ION PLASMA.** The decay of a whistler wave into an electron acoustic wave and lower hybrid wave in a hot-ion plasma is considered. The growth rate of the decay instability is calculated and shown to be comparable to those of other parametric instabilities. The importance of whistler waves in ionospheric and space physics is well known. These waves can sometimes be generated at very large amplitudes by beams of anisotropies in the plasma. It is therefore of interest to study the non-linear behavior of the whistler waves. (Edited author abstract) 11 refs.

**079609 ANCHOR PLASMA BUILDUP BY USING CENTRAL CELL ICRF ANTENNAS IN THE TANDEM MIRROR GAMMA 10.** The paper presents a study of anchor cell plasma buildup in the tandem mirror GAMMA 10 with the use of central cell ICRF antennas. For plasma buildup, it is demonstrated that an ion cyclotron resonance layer exists within the closed mod-B surface in the minimum-B anchor cell. The experimental plasma buildup rate in the anchor cell is compared with a one-dimensional Fokker-Planck simulation. A rapid increase in the anchor plasma density is observed and an associated reduction of the end-loss current when radio-frequency is applied. (Author abstract) 19 refs.

**079610 INFLUENCE OF A SUPERHERMAL TAIL UPON ECRH IN THETJ-II FLEXIBLE HELIAC - A THEORETICAL STUDY.** A superthermal tail is simulated by adding a drifted Maxwellian distribution to a bulk Maxwellian distribution  $f_0 = (1-\mu)f_b + \mu f_t$ . The values of the tail temperature ( $T_t$ ), drift velocity ( $v_0$ ) and weight coefficient ( $\mu$ ) are chosen so as to reproduce the

experimental residual current observed in the Wendelstein VII-A stellarator. An analytical expression for the resulting dielectric tensor coefficients is obtained. It is shown that, even for small tails, the global absorption coefficient increases for both the first harmonic ( $\omega = 28$  GHz) and the second harmonic ( $\omega = 56$  GHz) propagation. The effect is more dramatic for wave propagation in the first harmonic. The spatial bandwidth of the absorption region increases sensibly with respect to the pure Maxwellian distribution in both harmonics. (Author abstract) 16 refs.

**079611 ON REFLECTION FROM A SUDDENLY CREATED PLASMA HALF-SPACE: TRANSIENT SOLUTION.** The reflection by a suddenly created plasma half-space of a time-harmonic plane electromagnetic wave propagating in free space is considered. The problem involves a temporal discontinuity, a spatial discontinuity, and a dispersive medium. The steady-state solution is obtained by considering the basic features of the scattering processes due to each of the discontinuities in terms of analogous transmission-line models. The electric field of the reflected wave consists of two components. One component (called component A) is of the same frequency as the incident wave frequency and is due to the spatial discontinuity. The other component (called component B) is of a different frequency and arises because of the temporal discontinuity. The B component is damped out even if the plasma is only slightly lossy. The damping rate of the B component is calculated. The transient solution is obtained through the use of Laplace transforms. The solution is given in terms of Bessel-like functions. The limiting value of this solution is shown to agree with the steady-state solution. Numerical results illustrating the transient effects are for two typical cases. 8 refs.

**079616 OPTIMUM TOROIDAL PHASING FOR STABLE LOADING OF AN ICRF WAVE IN JT-60.** The propagation and absorption of the ion cyclotron range of frequencies (ICRF) waves, which are launched by toroidal-phased antennas, were studied in a JT-60 plasma. The second ion cyclotron resonance in a one-dimensional pure hydrogen plasma was considered by solving the kinetic wave equation. The dependence of the loading resistance on the antenna phasing as well as on the plasma parameters was obtained by numerical calculation. A model of a transmission line was introduced in our analysis. The optimum phasing and the plasma parameter region were obtained for a stable loading. Furthermore, it is shown that a combined heating with the neutral beam injection (NBI) makes the stable loading region wider. (Author abstract) 18 refs.

**079618 SPECTRAL CHARACTERISTICS OF HYDROMAGNETIC WAVES IN THE MAGNETOSPHERE.** This work is intended to explain why the resonant response of the magnetosphere prefers to have discrete frequencies. Using a cylindrical model for the outer magnetosphere with a plasma density profile proportional to  $1/r^3$ , we show that the eigenequation characterizing the eigenmodes of the hydromagnetic waves in this model has two turning points along the radial axis. The locations of the turning points depend upon the values of the eigenperiod and the associated east-west wavenumber of the eigenmode. The energy spectrum of the excited cavity modes is seen to have sharp peaks at discrete frequencies when the surface perturbations have a uniform spectrum in the frequency range of interest. The most likely values of east-west wavenumbers and wave period range are determined. (Edited author abstract) 24 refs.

**079620 NONLINEAR REGULAR STRUCTURES OF DRIFT MAGNETO-ACOUSTIC WAVES.** Nonlinear regular structures in a magnetized plasma connected with drift magneto-acoustic waves (DMA) are investigated theoretically. Three-dimensional nonlinear equations of weakly dispersive DMA waves are obtained. These equations contain both the scalar nonlinearity and the vector one, and generalize the two-dimensional Kadomtsev-Petviashvili (KP) equation. The existence is shown of regular stationary structures due to the scalar nonlinearity: one-dimensional solitons, two-dimensional rational solitons, chains of solitons and so-called 'crosses'. The stability of one-dimensional DMA solitons is investigated. It is shown that soliton stability depends on the sign of the wave dispersion as in the case of systems described by the KP-type equation. (Author abstract) 24 refs.

**079621 DISPERSION ION-DRIFT HYDRODYNAMICS.** The set of hydrodynamic equations for the ion component of a magnetized low-pressure plasma, including the nonlinear ion drift and waves related to it, taking into account dispersion effects of order  $k_1^2 p_i^2$  ( $k_1$  is the characteristic transverse wavenumber and  $p_i$  is the ion Larmor radius), is obtained. The reduction of these equations using the standard assumptions of vortex theory is given. The problem of the integrals of motion of the simplified equations is discussed. Account is taken of the gravitational force (which models curvature of the magnetic field lines), the three-dimensionality of the perturbations (drift-Alfven effects) and plasma rotation. It is suggested that the ion-drift hydrodynamics discussed here should be the basis for the analysis of the ion drift and the vortices related to it, as well as for the theory of decay processes with participation of the ion-drift waves. (Author abstract) 23 refs.

**079622 VORTICES OF ION-DRIFT AND RELATED WAVES.** The problem of vortices of ion-drift and related flute-drift, balloon-drift and drift-Alfven waves is analyzed, taking into account the finiteness of the Larmor radius of the ions. It is shown that the structure of the stationary ion-drift vortices is similar to that of the Alfven waves. It is found that the stationary ion-drift vortices in a plasma confined in a curvilinear magnetic field are characterized, generally speaking, by two different spatial scales. The role of plasma rotation in the vortex problem is investigated. (Author abstract) 22 refs.

Lakhin, V.P. (Space Research Inst, Moscow, USSR); Makurin, S.V.; Mikhailovskii, A.B.; Onishchenko, O.G. *J Plasma Phys* v 38 pt 3 Dec 1987 p 407-425.

**079623 ENVELOPE SOLITONS OF SURFACE WAVES IN A PLASMA COLUMN.** The problem of envelope solitons of surface waves is considered on the basis of results for the nonlinear dispersion relation of the waves in a plasma column. The soliton solutions are derived as particular cases of the general solutions obtained by a universal procedure and expressed in terms of Jacobi elliptic functions. Since the two types of

interactions, namely the  $(\omega + \omega) - \omega$  and the  $(\omega - \omega) + \omega$  interactions (where  $\omega$  is the frequency of the carrier wave) included in the nonlinear dispersion relation act in opposite ways, existence both of bright and dark solitons is shown to be possible. The effect of the ponderomotive force that in our case is expressed through the contribution of the  $(\omega - \omega) + \omega$  interaction leads to the formation of dark solitons. The effect of the losses is also considered. (Author abstract) 21 refs.

**079624 TWO-DIMENSIONAL ION ACOUSTIC SOLITARY WAVE IN A WEAKLY RELATIVISTIC PLASMA.** The two-dimensional Korteweg-de Vries equation is first derived for a weakly relativistic ion acoustic wave propagating in a collisionless plasma. We show that the relativistic effect greatly influences the phase velocity, the amplitude and the width of a solitary wave solution, and that the presence of streaming ions gives rise to the formation of a precursor. We also discuss three limiting cases of the present results. (Author abstract) 10 refs.

**079625 OBSERVATION OF LARGE-AMPLITUDE ION ACOUSTIC SOLITARY WAVES IN A PLASMA.** Propagation of nonlinear ion acoustic waves in a multi-component plasma with negative ions is investigated in a double-plasma device. When the density of negative ions is larger than a critical value, a broad negative pulse evolves to rarefactive solitons, and a positive pulse whose amplitude is less than a certain threshold value becomes a subsonic wave train. In the same plasma, a positive pulse whose amplitude is larger than the threshold develops into a solitary wave. The critical amplitude is measured as a function of the density of negative ions and compared with predictions of the pseudo-potential method. The energy distribution of electrons in the solitary wave is also measured. (Author abstract) 17 refs.

**079628 ION-ACOUSTIC SOLITONS IN MULTI-COMPONENT PLASMAS INCLUDING NEGATIVE IONS AT CRITICAL DENSITIES.** Ion-acoustic solitons in a plasma with different adiabatic ion constituents and isothermal electrons are studied via a reductive perturbation method. The basic fluid equations then give

rise to KdV or modified KdV equations, depending upon the relative ion densities. At critical densities, rarefactive and compressive fast ion-acoustic solitons are possible. Explicit stationary solutions are discussed in the special case of cold ions, in a plasma containing two species of negative ions and one of positive ions. The inclusion of heavier ions, even at low densities, increases the amplitudes of the critical solitons. (Author abstract) 9 refs.

**079629 HAMILTONIAN THEORY OF THE GENERALIZED OSCILLATION-CENTRE TRANSFORMATION.** The theory of the slow reaction of a charged particle in the combined presence of a strong quasi-static magnetic field and a high-frequency electromagnetic field (generalized oscillation-centre motion) is constructed by using a Hamiltonian formalism with non-canonical variables and pseudo-canonical transformations. The theory combines the features studied in our previous works for the case in which only one of the previously mentioned fields is present. The new averaging transformation is based on the fact that the Larmor frequency of the quasistatic field is of the same order as the external frequency of the high-frequency field. Our theory is manifestly gauge-invariant and involves only physical quantities (particle velocity and electromagnetic fields). Explicit expressions for the drift velocity of the oscillation centre and for the ponderomotive force are derived. (Author abstract) 14 refs.

**079630 ELECTROSTATIC ROSSBY-TYPE ION PLASMA WAVES.** It is shown that a plasma in which the background magnetic field varies in a direction perpendicular to its line of action can support 'Rossby-type' electrostatic waves at frequencies very much less than the ion gyrofrequency. The interesting dispersive and anisotropic features of these waves are revealed by the properties of their wave operators and described in terms of the geometry of their wavenumber surfaces. Since these surfaces intersect, inhomogeneity or nonlinearity will give rise to strong mode-mode coupling in regions where the phases of both modes nearly match. (Edited author abstract) 13 refs.

**079631 MEAN-FIELD MAGNETOHYDRODYNAMICS ASSOCIATED WITH RANDOM ALFVEN WAVES IN A PLASMA WITH WEAK MAGNETIC DIFFUSION.** Using first-order smoothing theory, Fourier analysis and perturbation methods, a new equation is derived governing the evolution of the spectrum tensor (including the energy and helicity spectrum functions) of the random velocity field as well as the ponderomotive and mean electromotive forces generated by random Alfvén waves in a plasma with weak magnetic diffusion. The ponderomotive and mean electromotive forces are expressed as series involving spatial derivatives of mean magnetic and velocity fields whose coefficients are associated with the helicity spectrum function of the random velocity field. The effect of microscale random Alfvén waves, through ponderomotive and mean electromotive forces generated by them, on the propagation of large-scale Alfvén waves is also investigated by solving the mean-field equations, including the transport equation of the helicity spectrum function. (Author abstract) 7 refs.

**079635 SOLITONS IN AN ION-BEAM PLASMA.** It is shown that the conservation law for total momentum of an ion-beam plasma system can be cast in the form of a classical energy integral of a particle in a potential well. By using boundary conditions appropriate to a solitary pulse, we derive conditions for the existence of finite-amplitude solitons propagating in the system. Under suitable conditions, as many as three forward-propagating solitary waves can exist. It is interesting to note that the criterion for their existence is intimately related to the absence of convective instabilities in an ion-beam plasma. Exact 'sech<sup>2</sup>' type solutions are available in the weakly nonlinear regime. Solitary-wave profiles for the general case are obtained numerically. (Author abstract) 9 refs.

**079636 PROPERTIES OF WAVES IN AN ION-BEAM PLASMA SYSTEM.** In this paper a multi-fluid approach is used to describe electrostatic interactions in an ion-beam plasma system. The structure of the wave equation governing the system exhibits the anisotropic and dispersive nature of the waves, whose properties are analysed in terms of the dispersion relation. The main purpose of this paper is to classify the different waves that can arise in an ion-beam plasma system in a systematic fashion. The classification is facilitated by introducing a three-parameter CMA diagram that illustrates the topological changes in not only the wavenumber, or refractive-index, surface but also the ray-velocity surface. Furthermore, an analytic expression governing wave amplification in an ion-beam plasma is incorporated within the framework of a generalized CMA diagram. Such a description provides a simple interpretation for the onset of wave amplification in terms of a topological change in the refractive-index surface. (Edited author abstract) 35 refs.

**079638 THEORY OF BERNSTEIN WAVE COUPLING WITH LOOP ANTENNAS.** Coupling to ion Bernstein waves near the first harmonic of the ion cyclotron resonance with coil antennas is investigated by using a plane layered model of a tokamak plasma. The boundary conditions in vacuum are solved analytically for arbitrary orientation of the antenna and Faraday screen conductors, in terms of the surface impedance matrix of the plasma for plane waves. The latter is evaluated by solving the wave equations in the plasma by taking into account finite Larmor radius and finite electron inertia effects, cyclotron and harmonic damping by the ions, and Landau and collisional damping by the electrons. Applications to the Alcator C tokamak give reasonable agreement between the calculated and measured radiation resistance when the first ion cyclotron harmonic is just behind the antenna; outside this range, the calculated resistance is lower than the experimental one. In general, the coupling efficiency is found to be very sensitive to the edge plasma density, good coupling requiring a low density plasma layer in the vicinity of the Faraday screen. **079640 NEAR-MAGNETOSONIC ENVELOPE UPPER-HYBRID WAVES.** A systematic analysis of envelope upper-hybrid wave propagation near the magnetosonic speed has been presented. Using the full set of fluid equations for the low-frequency dynamics, we obtain various model nonlinear equations describing the magnetosonic response to the envelope waves. In particular, we derive driven KdV as well as driven Boussinesq equations that are valid for near-magnetosonic propagation. Exact stationary solutions of the coupled equations are explicitly obtained. It is shown that a new class of upper-hybrid solitons with antisymmetric wave envelope exist for near-magnetosonic propagation. Integral invariants for the driven KdV case have been obtained and evaluated for localized solutions. A set of stationary governing equations is derived that takes account of the full nonlinearity in the low-frequency response as well as departures from the frozen-in-field approximation. A detailed comparison of the various model equations as well as their validity has been made. (Edited author abstract). 28 Refs.

**079642 ANALYTICAL SOLUTIONS FOR OBLIQUE WAVE GROWTH FROM A RING-BEAM DISTRIBUTION.** Analytical solutions are presented for the linear growth rate of oblique plasma waves in a magnetized plasma due to resonant interactions with a model ring-beam distribution. Explicit closed-form solutions for the angular dependence are obtained in terms of modified Bessel functions of the first kind. In the limits of either quasi-longitudinal or quasi-transverse propagation the analytical solutions take the form of simple algebraic expansions. The results can be applied, for instance, to the growth of waves following ionization of neutrals originating from cometary, planetary, or interstellar material in the solar wind. In a weakly unstable plasma the analytical results also provide an important check on the complex numerical codes that hitherto constituted the only method available for evaluating the growth of oblique plasma waves. (Edited author abstract). 20 Refs.

**079650 ON THE VALIDITY OF SAINT VENANT'S PRINCIPLE IN FINITE STRAIN PLASTICITY.** Diffusion of effects from a local disturbance in a homogeneous stress field is analyzed within the framework of continuum plasticity. An axial rate of decay for the variability of the effects of a nonuniform disturbance imposed on one end of a long circular cylinder is determined as a function of the axial stress (or stretch). The analysis considers constitutive equations corresponding to incompressible, finite strain versions of  $J_2$  flow and deformation theories. Both theories result in effects that oscillate and decay exponentially with distance from the imposed disturbance; the rate of decay decreases as the uniaxial tension increases. Deformation theory predicts a larger rate of decay than flow theory except within a small range of stress near the ultimate (necking) load; at necking the rate of decay vanishes. (Author abstract) 7 refs.

## Computation

**079653 PLASTICITY COMPUTATIONS USING THE MOHR-COULOMB YIELD CRITERION.** The paper describes the derivation and application of a range of numerical algorithms for implementing the Mohr-Coulomb yield criterion in a non-linear finite element computer program. Emphasis is placed on the difficulties associated with the corners of the yield surface. In contrast to the more conventional forward-Euler procedures, a backward-Euler integration technique is

adopted. A range of methods, including a 'consistent approach' are used to derive the tangent modular matrix. Numerical experiments are presented which involve solution algorithms including the modified and full Newton-Raphson procedures, 'line-searches' and the arc-length method. It is shown that the introduction of efficient integration and tangency algorithms can lead to very substantial improvements in the convergence characteristics. (Author abstract) 28 refs.

**079654 RESEARCH NOTE ON A REEXAMINATION OF NEUTRAL LOADING EXPERIMENTS.** In the examination of the published results from neutral loading experiments, the question as to whether plastic deformation occurs is found to depend on both the material and initial loading strain. Provided that initial loading is elastic, then a subsequent stress path that follows the boundary of the initial yield surface for a hardening material is truly neutral with a wholly elastic response. However, when initial loading is elastic-plastic, then further plastic deformation is produced from a subsequent stress path that follows an isotropic expansion of the initial yield surface. These results enable the appropriateness of the kinematic hardening rule and more recent developments in plasticity theory to be appraised. Neutral loading of a non-hardening material produces plastic flow. Whether the absence of hardening is inherent or induced by plastic prestrain, it is shown that the Prandtl-Reuss theory then represents the observed behavior. In general, the purely elastic and nonhardening solutions provide respectively lower and upper bounds on the deformation. (Author abstract) 15 refs.

**079656 PHENOMENOLOGICAL MODEL OF CREEP AND PLASTIC DEFORMATION.** A generalized model of creep and plastic strain which is based on the concept of the material damage is developed. Failure of the material is considered first of all as a state of complete exhaustion of the local plasticity of the material caused both by concentration of strain which is induced by the material inhomogeneity and by concentration of strain which is induced by relaxation of the stress peaks formed during the inhomogeneous material loading. This effect is strengthened by other physical and chemical processes of degradation, formation of discontinuities and microcracks caused by the exhaustion of the deformation ability of the material. **079657 CYCLIC PLASTICITY: THE CYCLIC NONHARDENING REGION MODEL.** With a set of material constants determined from strain-controlled experiments, predictions of a constitutive model are calculated for several kinds of stress- and strain-controlled cyclic loadings, and compared with the corresponding experimental results. The model describes accurately the cyclic plastic behavior of 304 stainless steel at room temperature. The cyclic stress-strain curve calculated for constant stress-ranges coincides with that for constant strain-ranges, as observed in the experimental results. (Author abstract) 13 refs.

**079658 ADVANCED APPLICATIONS OF BEM TO THREE-DIMENSIONAL PROBLEMS OF MONOTONIC AND CYCLIC PLASTICITY.** An advanced formulation of the boundary-element method (BEM) has been developed for three-dimensional inelastic analysis under both monotonic and cyclic loading. The analysis uses isoparametric shape functions to model complex geometries and rapid functional variations accurately. The numerical integration of the kernels are carried out by devising suitable automatic sub-segmentation which controls the error in the integration. The formulation has been applied to a number of three-dimensional elastoplastic problems involving monotonic and cyclic loading to demonstrate that it can be used for realistic engineering plasticity problems. (Author abstract) 29 refs.

**079659 METHODS OF ELASTIC SOLUTIONS.** The method of elastic solutions has been proposed for the solution of problems of the theory of small elastic-plastic deformations. This iterative process has proved to be an efficient method of solving boundary value problems for systems of quasi-linear differential equations of elliptic type. This paper considers a specific version of a method previously proposed as applied to the solution of quasi-static problems of the theory of small elastic-plastic deformations and offers a practical comparison of their convergence. 34 Refs.

**079660 INCORPORATION OF YIELD SURFACE DISTORTION INTO A UNIFIED CONSTITUTIVE MODEL, PART I: EQUATION DEVELOPMENT.** The multiaxial MATMOD-4V model has been modified to enable the predictions of distorted small strain offset yield surfaces. This has been achieved by using a variable Hill-type anisotropy tensor, which modifies the yield function in the model. Allowing  $M_{ij}$  to be a function of both the short and long range back stresses (the kinematic hardening variables in the model) results in an evolution of anisotropy during deformation. This improved model retains its capability to predict expansion and translation of the yield surface, as well as a wide variety of mechanical behavior described previously. The derivation of this model is presented. This work is pertinent to metal forming. (Edited author abstract) 16 refs.

**079661 MODEL FOR FINITE-DEFORMATION PLASTICITY.** We propose a new large deformation viscoplastic model which includes the effects of static and dynamic recovery in its strain rate response as well as the plastic spin in its rotational response. The model is directly obtained from single slip dislocation consider-

ations with the aid of a maximization procedure and a scale invariance argument. It turns out that the evolution of the back stress and the expression for the plastic spin are coupled within the structure of the theory. The model is used for the prediction of non-standard effects in torsion, namely the development of axial stress and strain as well as the directional softening of the shear stress. ## Radiation Effects

**079662 BASIC STUDY OF PLASTIC STRAIN FREEZING BY PHOTOPLASTIC EXPERIMENT.** It is difficult to solve the problem of stress-strain distribution in plastic regions in comparison with elastic bodies. Thus, an attempt to expand and apply stress-strain analysis by photoelasticity, with regard to polycarbonate resin in plastic photoelasticity, has been promoted so far and many significant achievements have resulted therefrom. This study is an examination of the possibilities of the plastic strain freezing method in comparison with the elastic stress freezing method. First, we attempted to determine the best temperature for plastic strain freezing. Further, it became apparent from systematic experimental results that it is 'strain' and not 'stress' which is frozen in plastic regions. In other words, it was made clear that the Birefringence  $N$  in strain freezing was proportional to the difference in the principal strains ( $\epsilon_1 - \epsilon_2$ ). (Author abstract) 7 refs.

## Strain

**079663 RESEARCH NOTE ON A COMPLIANCE APPROACH TO ANALYSIS OF PLASTIC STRESS-STRAIN RELATIONSHIPS.** The dependence of normalized compliance on strain is shown to be a discriminating pointer to the type of equation that can best match stress-strain data and also to the limit of stable uniform strain. An objective solution of the general power equation may be obtained by a relatively simple numerical analysis of the compliance strain relationship. The compliance approach permits valid statistical analysis of normally incremented test data (whereas analysis of logarithmic relationships properly requires exponential selection of the measured values). (Edited author abstract) 18 refs.

**079664 NOTE ON PLASTICITY THEORY IN MATRIX NOTATION.** In the matrix formulation of continuum mechanics, stress and strain tensors are contracted to vectors, and this lower order formulation has some advantages. However, due to an inconvenient contraction, the matrix formulation cannot be fully utilized in the theory of plasticity. The traditional contraction with engineering strains is rather artificial, and in the present note it is shown how the natural  $\sqrt{2}$  contraction for both stresses and strains makes a very clean formulation

possible. The importance of projection matrices is pointed out. (Author abstract) 2 refs.

Pedersen, Pauli (Technical Univ of Denmark, Lyngby, Den). *Commun Appl Numer Methods* v 3 n 6 Nov-Dec 1987 p 541-546.

**079665 ON THE APPLICATION OF THE PLASTIC SPIN CONCEPT FOR THE DESCRIPTION OF ANISOTROPIC HARDENING IN FINITE DEFORMATION PLASTICITY.** The aim of the paper is to fill the gap between the general theoretical formulation of the constitutive relations for plastic spin and practical applications for proper prediction of material behavior at finite plastic deformations and anisotropic hardening. An approximation to the representation of the general constitutive equation for plastic spin is considered and the pertinent substructure corotational rate is applied to formulate the relation for rigid-plastic material with kinematic hardening. The simple shear traction problem is analysed and the proposed model is verified with the experimental results of Swift. The merits of the present proposal vis-a-vis the existing theories are discussed. (Author abstract) 31 refs.

**079666 COROTATION DERIVATIVES AND DEFINING RELATIONS IN THE THEORY OF LARGE PLASTIC STRAINS.** Interest in elastoplasticity with large strains, by which the author means deformations with strain gradients exceeding (componentwise) 0.1, has increased markedly in the last decade. The main problem addressed by the theory of large elastoplastic strains in the derivation of the defining relations, in whose formulation some types of objective differential measures of the stressed and strained states, called corotational in the literature published abroad, are widely used. In this paper corotational derivatives are defined in an unified manner, and A.A. Il'yushin's theory of elastoplastic processes is extended to the case of large plastic deformations. 15 refs.

**079667 ON THE KINEMATICS OF FINITE-DEFORMATION PLASTICITY.** A theory of finite deformation plasticity is developed which involves a multiplicative decomposition of the deformation gradient through the assumption that there exists a stress-free configuration which can be used to separate the elastic and plastic components of the response. By using the polar decomposition on the usual indeterminate elastic and plastic deformation tensors, two uniquely defined stress-free configurations can be identified. The structure of this theory is compared with that of a spatial theory involving the polar decomposition of the total deformation gradient. (Edited author abstract) 19 refs.

**079668 ISOMORPHISM OF TRINOMIAL RELATIONS OF THE PLASTICITY THEORY AND SOLVABILITY CONDITIONS OF BOUNDARY VALUE.** For a trinomial relation of the general theory of plasticity, the theorem is proved of the isomorphism of the images of the process in the spaces of stresses and strains under certain constraints expressed as material functions. The sufficient unique existence conditions in the small have been obtained for a generalized solution of the boundary value problem. Based on experimental data, material functions have been suggested that satisfy the conditions of the isomorphism theorem. (Author abstract) 6 refs.

**079669 APPLICATIONS OF TENSOR FUNCTIONS TO THE FORMULATION OF YIELD CRITERIA FOR ANISOTROPIC MATERIALS.** Yielding of anisotropic materials can be characterized by yield criteria which are scalar-valued functions of the stress

tensor and of material tensors, for instance, of rank two or four, characterizing the anisotropic properties of the material. Because of the requirement of invariance, a yield criterion can be expressed as a single-valued function of the integrity basis. In finding an integrity basis involving the stress tensor and material tensors, the constitutive equations are first formulated based on the tensor function theory. Since the plastic work characterizes the yield process, it is read from this scalar expression the essential invariants to formulate a yield criterion. Some examples for practical use are discussed in detail. (Edited author abstract) 33 refs.

Betten, Josef (Technical Univ Aachen, West Ger). *Int J Plast* v 4 n 1 1988 p 29-46.

**079670 THEORY OF PARTICLE-REINFORCED PLASTICITY.** A simple, albeit approximate, theory is developed to determine the elastoplastic behavior of particle-reinforced materials. The elastic, spherical particles are uniformly dispersed in the ductile, work-hardening matrix. The method proposed combines Mori-Tanaka's concept of average stress inelasticity and Hill's discovery of a decreasing constraint power of the matrix in polycrystal plasticity. Under a monotonic, proportional loading the latter was characterized, approximately, by the secant moduli of the matrix. The theory is established for both traction and displacement-prescribed boundary conditions, under which, the average stress and strain of the constituents and the effective secant moduli of the composite are explicitly given in terms of the secant moduli of the matrix and the volume fraction of particles. (Edited author abstract) 33 refs.

**079671 NUMERICAL STUDY OF HOLONOMIC APPROXIMATIONS TO PROBLEMS IN PLASTICITY.** The incremental holonomic boundary-value problem in elastoplasticity has been shown to be characterized by a variational inequality. The problem may be approximated, however, by a perturbed minimization problem, characterized by a variational equality. This formulation is used as the basis for constructing finite element approximations of the original boundary-value problem, leading to a system of non-linear algebraic equations. Procedures for solving these equations are described and numerical results are presented and compared with those obtained using a conventional approach. (Author abstract) 11 refs.

Griffin, T.B. (Univ of Cape Town, Rondebosch, S Afr); Reddy, B.D.; Martin, J.B. *Int J Numer Methods Eng* v 26 n 6 Jun 1988 p 1449-1466.

**079672 NUMERICAL SOLUTION OF THE EVOLUTION EQUATIONS OF DAMAGE AND RATE-DEPENDENT PLASTICITY.** The evolution equations of damage theory and viscoelasticity are stiff ordinary differential equations and present numerous difficulties when one attempts to solve them numerically. This is particularly true when cyclic loading effects are to be simulated as few numerical schemes are stable when significant jumps in stresses occur. The present paper explores the performance of several numerical schemes for solving these evolution equations and presents methods which provide both accurate and stable simulations of large classes of rate-dependent problems. **079674 OFFSET YIELD CRITERION FROM PRECURSOR DECAY ANALYSIS.** A yield criterion for waves of uniaxial strain generated under planar impact conditions is proposed. A plastic strain offset of 0.0002 produces values of the Hugoniot Elastic Limit (HEL) which are consistent with those obtained from computed stress-time profiles in a strain-rate dependent material. Numerical computations using a finite difference computer code illustrate that the decay of the amplitude of the propagating precursor elastic wave is a consequence of material strain-rate dependence. The HEL at distances far from the impact plane is shown to be independent of impact velocity and the form of the constitutive equation. (Edited author abstract) 7 refs.

**079676 DEVELOPMENT AND STUDY OF A SCREW PLASTICIZER FOR ASBESTOS-FILLED MATERIALS.** To design a screw-type plasticizer, the authors investigated different variants of charging of asbestos-filled materials into a plasticizing cylinder (or into a material cylinder), determined the dependence of the productivity on the screw rotation speed and on the plasticization pressure, and studied the mechanism of material movement in the screw channel and its effect on the temperature of the dose accumulated. The experimental data obtained show that the calculation and selection of the geometric dimensions of the conical screw should be made with due consideration for the particle size of the material and the compression characteristics of the asbestos-filled materials being processed. Investigations of the pattern of movement and compaction of the materials showed that the asbestos-filled material can be compacted in the charging area 3-5-fold by a conical screw. Based on the studies made, it can be concluded that a screw plasticizer should be used for processing the asbestos-filled materials 143-63L and 328-303. The experimental data can be used for designing new equipment for processing fiber-filled materials and for calculating the productivity and capacity of the charging area (depending on its design) of the plasticizer. 4 refs.

**079677 INTERACTIONS AND PARTITIONING OF LOW MOLECULAR WEIGHT POLYETHYLENE GLYCOLS AND DIETHYL PHTHALATE IN ETHYLCELLULOSE/HYDROXYPROPYL METHYLCELLULOSE BLENDS.** The interactions and partitioning of diethyl phthalate and low molecular weight polyethyleneglycols in blends of ethylcellulose/hydroxypropyl methylcellulose have been studied. Both plasticizers were shown to diffuse in both phases according to the overall volume composition. The plasticizers interacted preferentially with one polymer component of the blend as predicted from studies of the individual polymers. Diethyl phthalate, a preferential plasticizer for ethylcellulose, demonstrated increased partitioning in the ethylcellulose-rich phase only at 80/20 w/w ethylcellulose/hydroxypropyl methylcellulose compositions. Polyethylene glycols, PEG200 and PEG400, preferential plasticizers for hydroxypropyl methylcellulose, showed increased partitioning in the hydroxypropyl-methylcellulose-rich phase also in blends containing 80% w/w ethylcellulose. **079678 PLASTICISERS.** Demand for PVC in Western Europe totalled 4.24 million tons in 1986 of this, 1.53 million t (36%) was destined for plasticised PVC. The chief fields of application are cable insulation (0.38 million t/p.a.), film production (0.35 million t/p.a.) and the flooring industry (0.23 million t/p.a.). The different plasticisers on the market essentially fulfil the technical requirements placed on the service properties of plasticised PVC. Fundamentally new developments - like the development a few years ago of a di-isononylphthalate with properties previously unattained in this group - are the exception. Progress is being achieved in small steps with the improvement of existing products (such as improved alkyl sulphonic acid ester from phenol). In plasticised PVC processing, the aim is for compounding and processing to be carried out on an increasingly continuous basis. The technical advances in mixing units can be cited as an example of this. 11 refs.

**079680 PHASE EQUILIBRIUM AND THE STRUCTURE OF THE SYSTEMS POLYMETHYL-METHACRYLATE-PHOSPHATE PLASTICIZERS.** Refractometry, light scatter and the turbidity spectrum methods have been used to study the phase equilibrium and structure of polymethylmethacrylate-alkyl halogen phosphate plasticized systems. The material presented indicates that the dependence of light scatter of plasticized systems on concentration is of an extremal character. The fall in  $T_g$  on introducing plasticizers into PMMA due to the breakdown and disordering of the supramolecular structures of the polymer is accompanied by increase in light scatter and the size of the concentration fluctuations. The maximum values of light scatter and the concentration fluctuations correspond to solutions of critical composition. (Edited author abstract) 12 refs.

**Toxicity**

**079681 DEHP AND TOXICITY.** DEHP has a widespread use in flexible vinyls, serving as the workhorse plasticizer. Extensive studies have shown that DEHP has a very low order of toxicity. Originally, concern developed over the effect DEHP might have on the environment. In 1980 results of two-year feeding studies on rats and mice by NCI caused the emphasis to shift to health aspects of DEHP. Although evidence to date shows DEHP has extremely low order of toxicity (acute), is a minimal irritant to skin or eyes, and poses no hazard to the environment, the chemical industry will continue investigations of phthalate plasticizers. **079685 NEW ACCESSORY FOR THE INFRARED ANALYSIS OF PLASTIC MATERIALS.** When confronted with the problem of having to analyse an unknown plastic material, there can be little doubt that infrared spectroscopy is the ideal technique, and the hot pressed film method the most convenient means of sample preparation. The sample is heated until molten, then pressed into a thin film and allowed to solidify. As additive concentration are often low - perhaps 0.1% m/m - much thicker films are necessary and, if a quantitative analysis is required, films prepared from both the samples and standards must also be of constant thickness. Now, a new sample handling accessory has been introduced that can prepare films to various thicknesses and of accurate reproducibility, allowing full qualitative and quantitative analyses. The Philips Analytical Precision Plastics Film Press is a complete, compact system for the analysis of plastic materials. Dies are supplied for creating films of 20, 50, 100, 200 and 500 mm thicknesses.

**079689 ANTISTATISTIC AGENTS.** High volume and surface resistivity values have given plastics an important position as an insulating material in the electrical and electronics sector. However, in all processes in which plastics are separated from other media, these same structure-related properties result in the accumulation of high electrostatic charges on the surface. There are three ways in which the conductivity of plastics can be increased in order to avoid static charge: by surface application of an 'external' antistatic agent from a solution, by incorporating an 'internal' antistatic agent into the plastic and by incorporating additives with electronic conductivity (graphite, metals, organic semi-conductors). External and internal antistatic agents, together with the moisture from the air, usually produce a film with ionic conductivity. Additives with electronic conductivity are used when the surface resistance has to be below  $10^8 \Omega$ . For the conventional antistatic agents a growth rate parallel to that of the bulk plastics can be assumed. 12 refs.

**079690 POLYUREA BODY PANEL FOR ON-LINE PAINTING.** Polyurea technology, combined with proven RIM processing, allows economically viable production of vertical exterior body panels for volumes under 200,000 vehicles. The Dow Chemical Company has developed a series of polyurethane and polyurea materials to meet the specific assembly and paint oven requirements of the automotive industry. Polyurea HT can be utilized to produce body panels which can be on-line painted and assembled without major modification to most current

assembly plants. 9 refs.

**079691 WHAT IS NEW IN PERFORMANCE PLASTICS?** The field of performance plastics is showing remarkable vitality and growth, even though the participants find the price to be high in terms of technical and sales support required, together with high capital investment for plants. High-performance requirements exist in virtually all segments of the plastics field; the major end uses are in aerospace, automotive, business machines, electrical/electronics, food packaging, and medical applications. There will be continued pressure on the performance plastics from the lower priced materials which are countering with upgraded, modified, alloyed versions of their own. There is also increased competition between thermoplastics and thermosets as the result of material developments and process refinements.

## Biocompatibility

**079692 SHORT-TERM CELL-ATTACHMENT RATES: A SURFACE-SENSITIVE TEST OF CELL-SUBSTRATE COMPATIBILITY.** Mechanisms of cell deposition from a sessile liquid phase and adherence to various plastic substrates have been investigated by measurement of short-term (<120 min) cell-attachment rates. Sigmoidal attachment-rate curves were fit with a three-parameter variant of a logistic equation to quantify parameters related to initial rate and equilibrium-adherence. Comparison of adherence parameters for ionomer and polyethylene films, both with and without adsorbed fetal-bovine-serum proteins, demonstrated that surface carboxyl groups were important in protein adsorption and cellular adherence. (Edited author abstract) 41 refs.

## Biodegradation

**079693 MICROBIAL DEGRADATION OF SYNTHETIC POLYMERS, NYLON, POLYAMIDES, POLY(ETHYLENE OXIDE), POLY(VINYL ALCOHOL), AND POLY(PROPYLENE OXIDE).** Polycondensations of dimethyl L-tartrate or diethyl mucate with hexamethylenediamine were carried out in solution to form polyamides having pendant hydroxyl groups. Strain PA9-4 was isolated from soil, which utilizes the polyamides as the sole source of carbon. The degradation of the polyamides by this bacterium was examined and compared with that of nylon 1, nylon 3, nylon 6, and nylon 66. The strain also degraded other water-soluble synthetic polymers such as poly(ethylene oxide) (PEO) and poly(vinyl alcohol) (PVA). The relation between bio-degradation and the equilibrium hygroscopic degree of these synthetic polymers was also discussed. The strain was tentatively classified as a Corynebacterium bacterium on the basis of its morphological and cultural characteristics. (Author abstract) 29 refs. In Japanese.

**079694 COMPATIBILITY OF POLY(VINYL CHLORIDE) WITH POLYALKYLENEOXIDES. I. POLY(METHYLENE OXIDE) AND POLY(ETHYLENE OXIDE).** The compatibility of poly(vinyl chloride) (PVC) with linear polyethers is examined over the entire composition range. This study examines blends with

poly(methylene oxide) (PMO) and poly(ethylene oxide) (PEO) of medium (MMW) and high (HMW) molecular weight. The techniques used are dynamic mechanical analysis, DSC, and optical microscopy (phase contrast and polarizing). The results indicate that all polyethers show limited miscibility in the melt at high PVC contents. Proper analysis of the  $T_m$  data using the Kwei-Frisch and Hoffman-Weeks procedures allows the determination of the thermodynamic interaction parameter to be made, which is found to be close to zero for all pairs of blends. (Edited author abstract). 47 Refs.

## Blow Molding

**079695 AUTOMATED IN-MOULD WALLTHICKNESS MEASUREMENT (IMM).** The plastic industry produces a variety of large containers for which special safety regulations apply. Among these are canisters and drums for dangerous goods, shock-proof drums, and especially motor-vehicle fuel tanks. A minimum wall thickness is laid down in all acceptance specifications for these containers. Thus thickness measurement is an important element of the production process and in quality testing and control. Cooperation between Elbatainer, Ettlingen, a plastics processor, and Krautkramer, Huerth, a manufacturer of testing equipment, had the objective of automating ultrasonic thickness measurement, an operation previously carried out manually. The target is to carry out the measurement at the earliest possible time on the production line. The ideal position making the measurement is within the blowing mould itself. On the basis of results from comprehensive practical trials, a system of measurement has now been developed that delivers reproducible results under these difficult conditions.

Buchscheidt, W.K.; Walker, D. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 5-7.

**079696 BELIEVE IT OR NOT, ALL THESE PARTS ARE BEING BLOW MOLDED.** Designers increasingly are looking to blow molding for components that may be too costly to make in relatively short runs by injection molding or structural foam molding, or which require more strength and rigidity than can be developed in thermoforming. The most obvious advantage of the process (that it can make hollow parts of almost any shape) is being exploited in many new applications. The fact that such versatile performance is achieved in a structure with just two parts indicates the ability of blow molding to take advantage of the cost/performance benefits of parts consolidation. Although the great bulk of blow molded parts are made of polyethylene, structural designers now can choose from a broadening range of blow moldable engineering resins. One of the innate advantages of blow molding is that its tooling is lighter in weight and costs less than that of other processes.

Smoluk, George R. *Mod Plast* v 65 n 3 Mar 1988 p 72-74, 76.

**079697 ON-LINE MEASUREMENT AND ESTIMATION OF PARISON DIMENSIONS IN EXTRUSION BLOW MOLDING.** An optical on-line parison profile thickness estimation technique has been devised and found to agree well with data obtained from a pinch-off mold. The dynamic response of thickness distribution to steps of various magnitude, direction, and locations along the extrusion has been obtained. The technique will be utilized to obtain dynamic models required for closed loop control of parison dimensions. The technique was applied to the blow molding of polyethylene. 14 Refs.

## Calendering

**079698 A NUMERICAL ANALYSIS OF CALENDERING.** An analysis of calendering of inelastic (power-law) and viscoelastic sheets of finite initial thickness has been carried out using (i) a perturbation method based on lubrication theory; (ii) an approximate treatment including normal stress effects; (iii) a full numerical analysis using the boundary element method. The N. Phan-Thien - R.I. Tanner (PTT) fluid model was used in the viscoelastic analyses. Attention is focused on the separation criterion at the roll exit plane. While it is usual to assume in the inelastic case that separation occurs when the pressure and pressure gradient vanish simultaneously, it is not clear that this is appropriate in the viscoelastic model. The main new results are (a) a method of determining the separation point numerically using the criterion of zero tangential traction; (b) a computation of walling (approximately 5 percent) after the sheet leaves the nip; (c) a demonstration that the roll force first decreases as Weissenberg number (roll speed) rises, and then increases. (Author abstract). 24 Refs.

## Cleaning

**079699 NIEDERDRUCKPLASMA TECHNOLOGIE IN DER PRAXIS.** [Low Pressure Plasma Technology in Practice]. Low pressure plasma treatment is a simple, sure and at the same time versatile method for cleaning, modifying and conditioning the surfaces of a very wide range of materials. Microwave excitation can be used to effectively treat plastics without causing visible changes at the surface. Owing to the short processing times and the small amount of materials needed for running the equipment, the method is economical, the freedom from problems with respect to waste disposal and the safety of the workplace playing a significant role. (Author abstract) In German. 5 refs.

**079700 BARRIER COEXTRUSION GOES PUSH-BUTTON.** A discussion is presented of a new online spectrophotometric selective layer gage. The gage is designed for selective measurement of 3- and 5-layer films from 0.5-10 mils. It is claimed to provide measurement accuracies for barrier layers (plus two other layers) of  $\pm 10\%$  in films from 0.5 to 2 mils, and  $\pm 5\%$  in gages of 2 to 10 mils. The gage's sensor head contains a 16-bit microprocessor that conditions raw infrared wavelength signals via software programmed for spectrophotometric analysis. Also discussed is new sheet-specific coextrusion equipment including dual-lip profiling dies, split-entry feedbacks, plug-in supplier written software and, coex lines equipped with gear pumps.

Sneller, Joseph A. *Mod Plast* v 64 n 1 Jan 1987 p 34-37.

**079701 GEAR PUMP ASSISTED COEXTRUSION.** The gear pump, although not a cure-all, can offer definite benefits in many extrusion applications. In general, a gear pump should be considered for an extrusion process if one or more of the following conditions are present: poor

output stability; critical gauge dimensions; low extruder output; expensive resins; frequent product changes; regrind materials; high melt temperature or temperature sensitive processes; high head pressures; and coextrusion. Coextrusion is an ideal candidate for the melt pump due to the need for precise metering of layers, use of expensive resins, regrind materials, high head pressures, and temperature sensitive products. The use of multiple extruders presents special problems such as longer melt transition piping, which dictates higher head pressures. Multiple extruders also create special control and coordination requirements. The gear pump's linearity and predictable output make it an ideal candidate for this type of application. With the predictable output of the gear pump, line stability can be achieved in a much shorter time, resulting in decreased setup time, decreased scrap generation, and higher productivity. 6 refs.

Smith, Daniel J. (Luwa Corp, Charlotte, NC, USA). *J Plast Film Sheeting* v 4 n 1 Jan 1988 p 72-80.

**079702 COEXTRUDIERTE SPERRSCHICHTROHRE FÜR KRAFTSTOFFLEITUNGEN.** [Coextruded Barrier Layers in Fuel-line Tubing]. Length increase and fuel diffusion are disadvantages accompanying the use of polyamide (PA) 11 and polyamide 12 tubing for fuel lines. These problems have to be solved before steel tubing can be replaced by plastics tubing for this function. By coextrusion of suitable materials with barrier properties it is now possible to reduce the diffusion of fuels, and the length increases due to particular components of fuels. However, to achieve optimum technical and economic solutions by coextrusion, specific combinations of polymers are required for each type of fuel. (Author abstract) In German and English.

Brunnhöfer, Erwin (Caprano & Brunnhöfer KG, Fulda-bruck, West Ger); Egen, Uwe. *Kunstst Ger Plast* v 78 n 5 May 1988 p 407-410.

**079703 NEW TIE LAYERS BRIGHTEN LIFE FOR COEXTRUDERS.** The compatibility problem between the non-polar and polar materials - that is, the tie-layer base resin and the barrier resins - typically is handled by chemically modifying the tie layer backbone with 'functionality,' a molecule or chemical group having polar properties. The expansion in hot-fill and retortable applications has spurred the development of higher-temperature (or higher-strength) alternatives to ethylene-vinyl acetate (EVA) for bonding barrier resins and polypropylene (PP) for PP-EVOH or PP-nylon coextrusions. Du Pont now offers a new series; several resins for PVdC have been developed for rigid PP coextrusion; several tie-layer clear resins for PC have surfaced; for coextrusion-lamination with a variety of materials - PC, PP, PET and copolymers, EVOH, and nylon; Shell Chemical has developed a PP-PP elastomeric tie resin based on its styrene-butadiene block copolymer chemistry. Other newer developments in resins are described.

**079706 ASPECTS OF ORGANIC-COLORANT SELECTION FOR ENGINEERING POLYMERS IN THE AUTOMOTIVE INDUSTRY.** Where heavy-metal-containing pigments must be avoided, growing attention has been focused on organic colorants, especially in Europe. In the face of high melt temperatures, the boundary between organic pigments and dyes blurs, and products must be selected with great care. Migration-related problems are particularly troublesome. TGA screening procedures can be used to predict some aspects of migration behavior, as reported here for a series of dyes in polycarbonate and nylon. (Author abstract)

Sykes, Roger (Ciba-Geigy, Basel, Switzerland). *Plast Compd* v 10 n 2 Mar-Apr 1987 p 13-16, 18, 20-22.

**079707 COLORANTS.** Colorants include individual inorganic and organic pigments, soluble dyes and so-called programmed colorants. The latter are specific preparations or combinations for a particular plastic intended to provide a specified tone with the required light fastness. Individual colorants are used by plastics producers, compounders and plastics processors with in-house color laboratories. In addition there are companies who manufacture programmed colorants as a service to processors. Two developments have placed considerable demands on all manufacturers and users of colorants. The first is the vigorous development of engineering and high performance plastics which require better physical properties, particularly heat resistance. The second is caused by limitations resulting from legislation or discussions on ecological, physiological or toxicological aspects. 11 refs.

**079708 COMBUSTION PRODUCTS OF POLYMERIC MATERIALS VERSUS HEAT RELEASED BY POLYMER COMBUSTION IN THE CAB 650 CHAMBER.** This work describes the results of an experimental study carried out in order to determine whether the combustion chamber CAB 650 can be used to determine the amount of heat released during combustion. The results of such tests would permit characterization of polymeric materials with respect to the three most important effects of fire - heat, smoke and the toxicity of the combustion products. A method has been developed enabling comparison of polymeric materials on the basis of the heat evolved during combustion. The calculated heat index yields information on the heat capacity of the material compared with cellulose as a standard material. (Edited author abstract) 1 ref.

**079709 FEATURES OF EPOXY COMPOSITE IGNITION BY CONTINUOUS LASER RADIATION.** A study of the modified fire-resistant polymers with a solid-phase inhibitor action that alters the structure and properties of coke is of special interest. Tests were conducted on the effect of continuous laser radiation on the epoxy resin ED-20 solidified by metaphenylene diamine and containing a vanadium compound ( $V_2O_4$  and  $VC_3$ ) which are effective inhibitors of combustion. It should be noted that the mechanism of the action of these

admixture reduces to the acceleration of dehydrogenation and dehydration processes, whereupon the coke yield is increased significantly. 7 refs.

**079710 COMPUTER OPTIMIZATION OF FORMULATIONS.** Formulation, balancing the portfolio of additives to obtain the target level on each key physical property, is a difficult art. With recent advances in personal-computer hardware and software it can become more of a science; the problem can be transformed into a mathematical form suitable for solution on a computer. First, an experimental design technique is developed to generate data for modeling. Then each property can be modeled as a function of the level of each of the additives, constraints can be set on property values, and the problem can be structured to find the minimum cost formulation for a given set of physical-property constraints. This article demonstrates the methodology, with real examples using engineering resins and various levels of glass fiber and microspheres, and considers such properties as tensile and flexural strength and modulus, impact strength, density, warpage, and cost. 10 refs.

**079711 HIGH INTENSITY COMPOUNDING OF MICA-FILLED THERMOPLASTICS.** High-speed turbine mixers have been adapted for compounding filled thermoplastics by the partial flux method. The extreme shearing forces exerted by the mixing impellers simultaneously mixes and delaminates mica fillers to form finely dispersed compounds in a granular, partially fused state which can be directly injection molded without pelletizing. The partial flux method permits compounding to be accomplished at peak sensor temperatures that are considerably below the resin softening or melting transitions, frequently 50°C less than normal compounding temperatures. The short residence times and reduced energy requirements possible with partial fluxing results in substantial cost reduction without compromising quality or performance. Examples are provided for polypropylene, nylon 66, poly(butene terephthalate), poly(ethylene terephthalate) and poly(phenylene oxide) alloys. (Edited author abstract) 11 refs.

**079712 SPOTLIGHT: SOFTWARE CUSTOMIZES COMPOUND FORMULAS.** Roscom Inc., a compounder with a manufacturing facility in Trenton, N.J., has recently developed a custom software package that generates compound formulas to meet specific needs. For example, a client may require that a compound retain UV resistance for a specified period and remain within certain cost parameters. The requirements are keyed into a computer, and a customized software program works out a formula. Development of this program is part of a general upgrade under way to improve compounding capabilities, flexibility, and traceability.

**Computer Aided Analysis**

**079714 MOLDING OF A PLASTIC DATA BASE.** As blends and alloys proliferate, the task of selecting materials is becoming increasingly complex. A computer data base helps design engineers to predict how plastics will perform in actual operating conditions. Computers are an essential tool in tracking complex material and part behavior, but it is up to engineers to predict the performance of specific molded parts under actual operating conditions. In order to do so, they must have at their disposal accurate and relevant engineering data. (Edited author abstract)

**Computer Integrated Manufacturing**

**079715 CIM CONCEPT FOR INJECTION MOULDING.** A concept for the automation of injection moulding is described. To achieve fully automatic injection moulding production, the whole environment of the injection moulding machine must be incorporated into the automation concept. This begins at the mould store and extends from transport and preheating of the moulds and the automatic mould changing, through automated injection moulding with handling units for removing the mouldings, to automatic materials changing at the injection moulding machine and removal of the palettes filled with finished mouldings. The authors show such an automated production plant installed in the development, demonstration and training centre for injection moulding technology, with two injection moulding machines. This plant has also proved to be a test plant for implementation of accessories. It permits the user-friendliness to be examined and the use with new development techniques to be learnt, especially in the field of software technology. In English and German.

**079717 HIGHLY ELECTROCONDUCTIVE POLYPYRROLE COMPOSITES.** Following up our work on polypyrrole (PP), one of the few synthetic metals having a fairly good stability in air, we have tried to overcome

some of the limitations of its synthesis and handling. In the course of the study on the chemical polymerization of pyrrole to highly conducting PP we have found that by supporting the monomer on a porous substrate before contacting it with an oxidant solution, it was possible to improve the conductivity of the polymer formed. In terms of conductivity per gram of electroactive material, an improvement by a factor of up to 3 or 4 was achieved. 9 refs.

Bocchi, V. (Univ di Parma, Parma, Italy); Gardini, G.P.; Rapi, S. *J Mater Sci Lett* v 6 n 11 Nov 1987 p 1283-1284.

**079718 THERMAL STABILITY OF SHIELDING EFFECTIVENESS OF ELECTROMAGNETIC INTERFERENCE OF COMPOSITES.** A series of composites were prepared using polyethylene and various chatter-machined metal fibers (aluminum, copper, steel and brass) and carbon fiber, and the effects of the concentration of the fillers and the thermal treatment of the composites at 80°C in air on the shielding effectiveness (SE) of electromagnetic interference were examined. Thermal degradation of SE was scarcely observed in the carbon fiber system and very slightly in the brass and steel systems, while remarkable degradation was observed in the copper and aluminum systems. This degradation was assumed to be due to the formation of an oxidized surface to increase the contact resistance between fillers. Stabilization of the thermal degradation of SE of the aluminum composite was possible to some extent when the aluminum surface was pretreated with certain reagents. (Edited author abstract) 20 refs.

**079719 FILLER-CONTAINING, ELECTRICALLY CONDUCTIVE PLASTICS.** The objective of using plastics in increasingly new fields of technology has led in recent years to demands for plastics with custom-made electrical properties. The great interest in electrically conductive (and thermoplastically processable) plastics is explained by the fact that housing with integrated shielding can be produced in a single processing step. A step in the direction of achieving this objective is the incorporation of electrically conductive fillers into thermoplastically processable plastics. A conductive network of filler particles in the finished article is essential for the functioning of the shielding. The physical conditions and the problems involved in the formation of such a network are discussed. In English and German.

Moebius, K.-H. *Kunstst Ger Plast* v 78 n 1 Jan 1988 p 17-20.

**079720 ELEKTROMAGNETISCHE ABSCHIRMUNG MIT ELEKTRISCH LEITFAEHIGEN KUNSTSTOFFEN.** [Electromagnetic Shielding with Electrically Conductive Plastics]. Starting out with the objective of preventing mutual electromagnetic interference between electronic instruments with housings made from electrically conductive plastics, some fundamental principles of the shielding of electromagnetic fields and waves are discussed and a coaxial method of measurement for the determination of shielding efficiency under far field conditions is explained. For an interpretation of the corresponding measurements in the context of the properties of the shielding materials, consistent treatment of reflection and absorption of plane waves in the shield is necessary. This is explained by the use of a carbon black-filled model system. An ASA/PC-blend filled with Al-flakes is presented as an example of a construction material having high shielding efficiency. (Author abstract) 12 refs. In German.

**Crack Propagation** See Also ELECTRONICS PACKAGING—Thermal Effects; POLYMERS—Fracture.

**079722 EFFECT OF PHYSIOLOGICAL SALT WATER ON FATIGUE CRACK PROPAGATION RATE FOR GLASS FIBER REINFORCED POLYCARBONATE.** The fatigue crack propagation in physiological salt water was investigated in polycarbonate and glass fiber reinforced polycarbonate. The effects of physiological salt water, glass fiber content and stress ratio on fatigue crack growth rate were determined. These effects in physiological salt water could be considered by dividing the crack growth rate into two regions: I and II. The crack growth rate in region I was accelerated by the physiological salt water and stress ratio. In region II, the crack growth rate increased by increasing the content of glass fiber. The crack opening level in the physiological salt water decreased rapidly with increasing  $\Delta K$ . This transition behavior may result from the physiological salt water penetrating the fatigue crack, which deforms itself like a viscous fluid against a viscous elastic crack, and divides the crack growth rate into two regions. (Edited author abstract). 15 Refs. In Japanese.

**079723 CREEP INDUCED BUCKLING OF PLASTIC MATERIALS.** In this work, creep induced buckling was studied for a number of thermoplastic materials. The effect was observed by monitoring top displacements of thermoplastic bars a function of time under static loading conditions. The recorded times to failure were averaged and correlated with the applied loads. The experiments, conducted for different materials, established an exponential dependence between the critical time and the load. The evolution of the buckling eigenvalues was modeled numerically. The simulations of eccentric columns behavior under compressive loads were coupled with the eigenvalue analyses. The correlation of the time-load predictions obtained from the numerical simulations followed the experimental results within acceptable limits. The observed phenomenon of creep induced buckling was explained by damage accumulation leading to an effective reduction of the load carrying capability. (Author abstract) 12 refs.

**079724 TEMPERATURE DEPENDENCE OF LIFETIME STATISTICS FOR SINGLE KEVLAR 49 FILAMENTS IN CREEP-RUPTURE.** Experimental data are presented for the strength and lifetime under constant stress of single Kevlar 49 aramid filaments at 80 and 130°C. As seen in previously published work performed at room temperature (21°C), the strength data could be fitted to a two-parameter Weibull distribution; increasing the temperature caused a decrease in the Weibull scale parameter while the shape parameter remained relatively constant, indicating a decrease in the mean strength but no change in strength variability. Lifetime experiments were performed at different filament stress levels ranging from 55 to 92.5% of the Weibull scale parameter for short-term strength at that temperature. These data were fitted to a two-parameter Weibull distribution with large variability and evaluated using an

exponential kinetic breakdown model. Using this model, activation energies in the neighborhood of 80 kcal mol<sup>-1</sup> ( $3.35 \times 10^5$  J mol<sup>-1</sup>) were obtained, suggesting that scission of the C-N bond plays the dominant role in fibre failure at longer times under constant stress. (Author abstract) 36 refs.

## Database Systems

**079729 ENGINEERING DESIGN DATABASE FOR PLASTICS.** A readily-accessed data base provides valuable design information on a wide range of engineering resins, with properties keyed to application-specific conditions. GE Plastics has developed such a system and recently announced its availability to the design engineering community. This database will provide data on GE Plastics' Noryl modified polyphenylene oxide (PPO), Lexan polycarbonate (PC), Valox polyesters (PET, PBT), Ultem polyetherimide (PEI), Gelyo acrylonitrile-styrene-acrylic (ASA), Noryl GTX PPO/nylon alloy, Gemax PPO/PBT, Xenoy PC/PBT alloys, and Lomod thermoplastic copolyester elastomers. The Engineering Design Database (EDD) also includes GEFOAMS data on filled and unfilled structural foams.

**079730 SUMMARY OF THE NBS LITERATURE REVIEWS ON THE CHEMICAL NATURE AND TOXICITY OF THE PYROLYSIS AND COMBUSTION PRODUCTS FROM SEVEN PLASTICS: ACRYLONITRILE-BUTADIENE-STYRENES (ABS), NYLONS, POLYESTERS, POLYETHYLENES, POLYSTYRENES, POLY(VINYL CHLORIDES) AND RIGID POLYURETHANE FOAMS.** A series of literature reviews was undertaken by the National Bureau of Standards to examine the toxicity and chemistry of the effluents produced when seven plastics were decomposed under various thermal and atmospheric conditions. These plastics are: acrylonitrile-butadiene-styrenes, nylons, polyesters, polyethylenes, polystyrenes, poly(vinyl chlorides) and rigid polyurethane foams. The English-language literature on each of these was reviewed and published as a separate report of the National Bureau of Standards. Over 400 different thermal decomposition products, many common to more than one plastic, were identified. The toxicity of most of these individual products is unknown and an assessment of the toxicity of the multitude of possible combinations is not feasible at this time. Therefore a variety of bioassay toxicity protocols have been used to assess the toxicity of the gaseous atmospheres generated by the thermal decomposition of these plastics. ## Decoration

**079731 INNOVATIVE DECORATING CUTS COSTS, BOOSTS VALUE.** Many of today's decorating innovations are in response to the challenges posed by automotive style changes. Imaginative use of new in-mold decorating technology is helping automotive companies meet their goals to improve aesthetics and produce more cost-effective decorated plastic parts. Innovative decorators are also taking advantage of advances in hot stamp foils and heat transfer to eliminate decorating steps and reduce costs. The sublimation and Hydro GraFix processes and laser marking are finding new applications that make the most of their inherent advantages.

**079732 DEFORMATION BEHAVIOR OF HDPE/(P-PEC/PS)/SEBS BLENDS.** Immiscible blends of high

density polyethylene (HDPE) and an amorphous glassy phase consisting of either pure polystyrene (PS) or a miscible blend of PS and a polyether copolymer (PEC) were compatibilized with various amounts of a styrene-hydrogenated butadiene block copolymer (SEBS). Using a liquid displacement stress dilatometer, the volume change of samples during uniaxial mechanical straining was determined and related to the various modes of deformation. Blends were fabricated by both injection and compression molding. Microscopic evidence of the improved adhesion and modes of deformation agrees with the results obtained by dilatometry. The volume dilatation of compression-molded materials do not seem to be similarly affected by the composition of the glassy phase which may reflect morphological differences between injection- and compression-molded blends. (Edited author abstract) 28 refs.

**079734 STEADY STATE PENETRATION OF COMPRESSIBLE RIGID PERFECTLY PLASTIC TARGETS.** Steady state axisymmetric deformations of a homogeneous, isotropic, compressible and rigid perfectly plastic target being penetrated by a rigid cylindrical penetrator with a hemispherical nose are studied by the finite element method. The steady state is reached with respect to an observer situated on the penetrator nose and moving with it. Tillotson's equation, restricted to mechanical deformations, is used to express the pressure as a function of the mass density. Contact between the penetrator and the target is assumed to be smooth. The effect of compressibility of the material is delineated by comparing results for compressible and incompressible materials. Also studied is the effect of the penetrator speed on target deformations. (Author abstract). 10 Refs.

## Elastoplasticity

**079737 ANALYSES OF THE YIELD BEHAVIOR AND THE STRESS PATHS UNDER THE COMBINED STRESS LOADING IN POLYMERIC MATERIALS.** Non-plasticized PVC, ABS, and PMMA bars were subjected to various rates of stretch and twist. Experimental results were analyzed using the corrected Gaydon's equation. The results were applied to ideal elasto-plastic bodies that obeyed Hooke's law and Reuss's equation with yield points undergoing von Mises and Tresca criteria. Interaction curves were drawn in two dimensional stress space; these showed good agreement with the stress values of yield points obtained from the experiment. A method was derived to draw the interaction curves so as to satisfy, in a broad sense, the elasto-plastic model. The intersecting points between these curves and the stress state in stress space under the loading conditions suggest that a change in elasto-plastic state occurred during the deformation along the stress-strain curves. **079738 CONDUCTIVE PLASTICS CHARGE INTO NEW ELECTRONICS MARKET.** Conductive plastics are employed in the protection of electronic components and products, 5 to 25% of whose failures are related to electrostatic discharge (ESD). Conductive plastics are used to shield against electromagnetic interference and to dissipate ESD. Virtually all plastic materials can be made conductive with additives. However, some plastics are inherently conductive, but they are currently available only for special applications. There are two ways to measure the conductivity, or resistance, of a material: by the volume resistivity and the surface resistivity of the material. Some approaches to making inherently conductive plastics are described.

## Environmental Impact

**079741 VYUZITI PLASTU PRI DOPRAVE ZPRACOVANI GEOTERMALNICH VOD.** [Use of Plastics in Transport and Processing of Geothermal Water]. Results obtained by testing twelve samples of plastics in thermal water are presented in this paper. The results showed a high affinity of inorganic substances to plastics. Adhesion of the inorganic substances to the material and changes in mechanical properties of these materials were evaluated. The tendency of plastics towards incrustation is higher than that of steel. When incrustation inhibitors are used, the application of plastics does not give any advantages as the consumption of inhibitors in plastics is higher than that in steel. The advantage of plastics lies in their resistance to corrosive environment. (Edited author abstract) In Czech.

**079744 DIMENSIONLESS CURVES FOR EXTRUDER MELT TEMPERATURE AND FLOW.** An accurate analysis of the melt flow in the metering section of an extruder typically requires a computer simulation if the interaction of the melt temperature and pressure with viscosity is to be considered. A simple isothermal calculation can estimate flow rate, but does not give any information about melt temperature. A comprehensive simulation which does contain thermal information requires access to a computer and some amount of knowledge and effort in encoding the input and decoding the output. A technique for calculating extruder melt flow is presented here. It includes thermal and viscous effects in a graphical format and does not require computer capability. The results can be used to make flow calculations and also to make general observations about melt temperature and flow in extruder melt sections. (Author abstract) 5 refs.

**079746 PROCESS CONTROL OF PROFILE EXTRUSION USING THERMAL METHOD. PART I: MATHEMATICAL MODELING AND SYSTEM ANALYSIS.** An analytical model based on the heat penetration through the die wall was proposed to calculate the effect of die wall temperature on the flow of polymer melt in profile dies. Model prediction matched well with the experimental data measured from a modified Instron capillary rheometer. The model was applied to an extrusion line with an L-shaped profile die. Dynamic responses of the profile extrusion line based on this die were measured and modeled. The pairing of manipulated variables and controlled variables was analyzed. (Author abstract) 52 refs.

Yang, B. (Ohio State Univ, Columbus, OH, USA); Lee, L.J. *Polym Eng Sci* v 28 n 11 Mid-Jun 1988 p 697-707.

**079747 PROCESS CONTROL OF PROFILE EXTRUSION USING THERMAL METHOD. PART II: CLOSED LOOP CONTROL.** A rubberized polystyrene was extruded through a simple L-shaped profile die with one thin section and one thick section. Takeup speed was used to control the size of the extrudate, and die temperature was used to control algorithms, a dual single-loop feedback PI controller and a multivariable feedforward plus feedback control method (FFC), were carried out for set point changes of the extrudate shape and size, and load disturbances of screw speed. Results showed that the PI feedback controller was satisfactory

for long-term set point changes but not for load changes. The FFC worked well for load disturbances lower than 10 cycles/min. Owing to the slow dynamic response of die temperature, the shape loop can only be controlled for long-term disturbances. (Edited author abstract) 24 refs.

Yang, B. (Ohio State Univ, Columbus, OH, USA); Lee, L.J. *Polym Eng Sci* v 28 n 11 Mid-Jun 1988 p 708-717.

**079748 MODELING OF EXTRUSION WITH SLIP BOUNDARY CONDITIONS.** Slip at boundaries is possible in viscous flows; for instance, in the extrusion of foodstuffs, water-containing materials, and some polymers. There are two phenomenological descriptions of slip: The first is based on the presence of a very thin, low viscosity boundary layer and has been derived for capillary flow and extrusion; the second is based on a Coulomb-friction mechanism and has been derived for capillary flow only. After a survey of these results, the friction model is derived for the extrusion process. All calculations are as simple as possible: two-dimensional, Newtonian, isothermal, and with constant boundary layer parameters or coefficients of friction. A strong dependence of pumping characteristics and efficiency on the slip boundary conditions, and also on the extruder length in the case of friction, was found, especially when slip is only allowed for at the screw surface. Exercises like these may help in understanding abnormal extrusion behavior of slippery materials in practice. (Author abstract) 38 refs.

**079749 EXTRUSION PLANT FOR COEXTRUDED FILM.** A newly designed plant is described which produces five-layer film and is suitable for all kinds of technical packaging films with high barrier properties, particularly meant for the extended storage of foods. Thanks to its progressive design, this coextrusion plant has numerous processing technological facilities to offer. The extruders are mounted on a rotating platform. One extruder of 65 mm screw diameter (model 65CV/D) and two extruders of 50 mm screw diameter (model 50CV/24D) are capable of producing composite film consisting of five layers to the pattern A/B/C/B/A. With multi-layer film of the A/B/C/B/D extrusion pattern, the system is complemented by adding another extruder model 50CV/24D. Take-off equipments are designed to suit the following film dimensions: reel-widths of 1200 and 1500 mm (with or without calender haul-off); reel widths of 2000, 2500 and 3000 mm. These plants can produce all kinds of technical packaging films of high barrier properties, e.g. PE/coupling agent/PA/coupling agent/ionomer. At film thicknesses of 40 to 140 µm and a film width of 1 m, the output rate is approximately 120 kg/h. Some of the plant components are described subsequently. Various pieces of equipment are described. In English and German.

**079750 OCENA SPRAWNOSCI UKLADOW UPLASTYCZNIJACYCH W PROCESIE WYTŁACZANIA: CZ. I. KRYTERIA OCENY SPRAWNOSCI.** [Evaluation of the Efficiency of Plasticating Systems in the Extrusion Process: Part I. Criteria of Efficiency Evaluation]. The basic categories in the evaluation of efficiency of plasticating systems in extruders are output and cost of the extrusion process, as well as product quality. In relation to the last-mentioned category, the effect of the extrusion process parameters (temperature, pressure and flow intensity), with allowance for their variation in time, the effect of homogeneity of material composition (quality of intermixing) and the effect of rheological characteristics of the material (viscosity and elasticity), has been isolated. On this basis, the main criteria of the efficiency evaluation for plasticating systems

have been characterized and methods of their measurement are discussed. (Edited author abstract) 22 refs. In Polish.

**079751 FLEX DRIVES QUALITY ROUTE TO AUTOMOTIVE SUCCESS.** The article describes some successful projects that have led to the Taguchi methods becoming standard operating procedure at Flex Technologies. A 'Taguchi experiment' is designed to identify and eliminate sources of variation and reduce their effect. A designed experiment is one that proceeds by a rational and systematic identification of variables, rather than trial-and-error varying of factors. Taguchi has also boiled down the complex mathematical task of analyzing multivariable experiments with a series of plug-in statistical tools called orthogonal arrays. One of Taguchi's innovations is to provide manufacturers with a means to quantify quality from the customer's point of view, the quality loss function (QLF), a mathematical tool that relates deviation in product characteristics to the cost that a customer incurs due to the deviation.

Schlack, Mark (Plastics World, Newton, MA, USA). *Plast World* v 46 n 7 Jul 1988 p 48-53.

**079752 HOW TO GET 'NEW' EXTRUDERS AT A FRACTION OF THE COST.** The article describes how plastics plants can modernize their existing extrusion systems quickly and economically through remanufacturing services from equipment suppliers. Extrusion Technical Services is a new one-stop shopping service supporting the extrusion machinery aftermarket. It is geared toward fast response and staffed with extrusion specialists skilled in hands-on problem solving. The ETS Div. was formally established as a separate business enterprise in 1982, and now performs a number of services for the extrusion aftermarket. Two case studies are reviewed to illustrate what remanufacturers can do.

**079753 ABSCHAETZUNG DER ANTRIEBSLEISTUNG UND MASSETEMPERATUR.** [Conventional Single-Screw Extruders]. This paper presents approximation calculations, based on the total energy balance, for estimating the performance of conventional-model plasticizing units from the energy point of view. Apart from characteristic functions to describe the nature of heat introduction into the extrudate, the calculation also takes in geometrical characteristic values and the melt temperature at the screw tip. Experimental verification of the above calculations over a wide spread of machine and operating point data produces maximum deviation of  $\pm 15$  percent. The approximations presented are initially valid for simple multi-section screws. Only one of the screws was fitted with a Troester shear section, 2D in length. The results were within the scatter range mentioned above. It is thus possible to use the equations as a guide in this case as well. Further screw configurations with different shearing and mixing sections will need to be investigated, however, before significant statements can be made. (Author abstract). 13 Refs. In German.

Potente, Helmut; Fornefeld, Antonius; Michel, Peter. *Plastverarbeiter* v 39 n 5 May 1988 p 34-40.

**079754 UEBERWACHUNG DURCH MESSUNG DES SCHMELZEDRUCKES.** [The Extrusion Process]. The melt pressure build-up in the screw region plays a decisive role in ensuring a uniform transport of melt, in that it influences flow behaviour and the thorough mixing of the melt. Since the screw is rotating, however, periodic and non-periodic signals are superimposed on the measured pressure values. The evaluation of the measured signals can thus really only be performed with a computer. For slow-conveying or conventional extruders, characteristic pressure profiles are obtained that are a function of the geometric dimensions of the particular screw and process variables, such as melt temperature and melt state. For purposes of monitoring the long-term behaviour of

the extruder it is useful to log the steady-state pressure profile over the length of the cylinder, whilst if the dynamic processes in the pressure profile are logged, this will permit statements to be made on short-term behaviour. (Edited author abstract). 9 Refs. In German.

**079755 INTERFACE DETERMINATION IN BI-COMPONENT EXTRUSION.** The unidirectional flow of two immiscible fluids with different viscosities in a long die of arbitrary shape is considered. Mathematically, the problem has a continuum of solutions corresponding to arbitrarily prescribed interface shapes, but experimental evidence indicates the existence of a unique interface shape with the less viscous fluid encapsulating the more viscous fluid. With the introduction of the minimum viscous dissipation principle, which postulates that the amount of viscous dissipation is minimized for a given flow rate, the problem becomes a nonlinearly constrained optimization problem. A generalized reduced gradient/finite element method combination is used to predict the interface shape when two inelastic fluids are considered. The effect of the viscosity ratio and flow-rate ratio on the interface shape is examined for different die geometries. Inner layer breakup phenomena are predicted and explained for complex die geometries. (Author abstract). 19 Refs.

## Extrusion Molding

**079756 ABWEICHUNGEN BERUEHRUNGSLÖS MESSEN.** [Measurement and Control Unit for Profile Extrusion]. This paper presents a measurement and control unit with an optical measuring head that will monitor the swelling of the plastic upon output from the die, or the tailback of material between the die and the calibrating unit, and keep this constant by changing the take-off speed. In cases where it is necessary to regulate the extruder speed, this can be done by using a piece of equipment ancillary to the basic unit. The measurement and control unit has been developed to smooth out any proportional changes that come about during the extrusion process via the take-off speed. To ensure rapid notification of malfunctions, an outline recognition system has been incorporated which triggers an alarm when the target value has not been attained over a specific period of time. (Edited author abstract). In German.

**079758 FILLERS.** The development and applications of mineral and organic fillers for polymers during the last three years has followed more or less conventional lines. The steep fall in polymer prices since the middle of 1985, especially for polyolefins, has in some cases considerably reduced the economic advantages of using fillers. Despite

this, the filler manufacturers have intensified their efforts to bring improved products for increasingly specialized plastics applications on to the market. 16 refs.

Schlumpf, H.P. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 99-101.

**079759 DROP-WEIGHT TESTING: WHAT IT TELLS DESIGNERS.** Such factors as improper mixing of fillers and resin degradation lead to bimodal effects in drop-weight tests. In such cases, replacement of ASTM 'staircase method' by the Probit method-testing multiple specimens at several energy levels-helps to clarify findings. The Probit method is akin to Bruceton; apparatus and specimen failure criteria are identical. However Probit method specimens are tested in successive groups, with each group of from 20 to 40 specimens tested at the same energy level. The energy levels used must correspond to less than 10% and greater than 90% failure and three groups at energy levels between these two extremes. Test results are plotted as failure energy vs failure percentage on probability graph paper. The Probit technique requires significantly more test specimens: 100 to 150 vs 20 to 40 for the Bruceton technique. 3 refs.

**079760 MINERALS IN PLASTICS: MEETING THE CHALLENGE OF THE FUTURE.** The authors outline the means whereby plastics producers can improve their market position. The two avenues open are to work on process improvements that will reduce operating costs or to seek product modifications that can improve performance and thus expand the range of applications. Although process improvement is certainly an important avenue, product modification may represent the greatest potential. The roles of minerals and surface-modified minerals are examined.

**Finishing** See Also PAPERMAKING—Finishing.

**079762 PLASMA PRETREATMENT FOR PLASTICS.** Printing, painting, decorating or bonding of plastics, especially the newer engineering plastics, can be a challenging task. The same chemical structure that gives the engineering plastics their thermal stability often makes their surface resistant to the adhesion of paint or ink. Surface treatment with cold gas plasma can improve adhesion. Cold gas plasma is a highly reactive yet perfectly safe dry chemical process that represents an interesting surface treatment alternative for finishers and decorators of plastic products. Even though the plasma is very active, the process is simple, controllable and safe.

**Flame Resistance** See Also FLAME RETARDANT—S—Applications; FLAME RETARDANTS—Toxicity.

**079763 OXYGEN INDEX METHOD IN FIRE RETARDANCE STUDIES OF POLYMERIC MATERIALS.** The oxygen index test is a fundamental tool in basic research on polymer combustion and on mechanisms of fire retardance. Although the oxygen index should provide an evaluation of intrinsic flammability of polymeric materials, its response may depend on geometry of the specimen. This is shown by comparing the behavior of polypropylene fire retarded with different additive systems. The implication of such mechanistic studies is discussed. Furthermore, new measurements are proposed to be carried out with the oxygen index apparatus, which give parameters related to ease of ignition, behavior on forced burning, and thermal insulating characteristics of char developed on burning the material. (Edited author abstract) 14 refs.

## Fracture

**079767 FRACTOGRAPHY APPLIED TO POLYMERIC MATERIALS.** The practical application of fractography to the study of plastic failures is at a very early stage of development. To date, studies of plastic fracture have concentrated more on the mechanism of fracture than on the relationship of fracture-surface appearance to changes in test variables such as temperature, loading, strain rate and environmental conditions. Most research studies of the failure of plastics include

inspection of the fracture surfaces with optical and scanning-electron microscopes. Analysis of plastic failures is complicated by the viscoelastic nature of the materials. There are two predominant micro-mechanisms of deformation, called craze formation and shear yielding. If the deformation leads to breakage, the fracture surfaces can be examined for evidence of the cause.

**Friction** See Also FORGING MACHINES—Friction.

**079768 FUNDAMENTAL STUDIES ON THE WEAR OF THE PLASTIC MATERIALS FOR SLIDING BEARINGS AGAINST ALUMINUM SHAFTS (PART 1) - FRICTION AND WEAR PROPERTIES OF VARIOUS PLASTIC MATERIALS AND SURFACE DAMAGES OF MATING ALUMINUM.** Various plastic materials such as polytetrafluoroethylene (PTFE), polyetheretherketone (PEEK) and their composites were rubbed against aluminum. Then the effects of temperature on the friction and wear of the plastic materials, and the surface damages of the mating aluminum were examined. The desirable properties of the plastic bearings sliding against aluminum shafts were investigated. In experiments carried out in the temperature range from 296 to 573 K, filled PTFEs, such as graphite-filled PTFE, polyparaoxybenzoyl (POB) - or polyphenylene sulfide (PPS) - filled PTFE, and POB - or PPS-filled PTFE containing graphite, showed low specific wear rates less than  $10^{-5}$  mm<sup>3</sup>/N m, and their coefficients of friction were lower than 0.3 without damaging the mating aluminum surfaces. PTFE-filled PEEK also showed good tribological properties at temperature of 296 K to 523 K. It seems that good sliding bearings show excellent wear resistance and form strong transferred films on the mating surfaces. When sliding experiments are carried out between plastics and their transferred films, the aluminum substrates seem not to be damaged by the plastics. (Edited author abstract) In Japanese. 16 refs.

**079773 INJECTION-MOLDING PROCESS CONTROL - A REVIEW.** This paper reviews control strategies employed in the injection-molding process. For clarity, the controlled variables have been categorized into all-phase control, phase-dependent control, and cycle-to-cycle control. All-phase control includes variables that must be monitored and controlled at all times; i.e., in all the phases. Control of variables that are triggered during a specific phase are discussed under phase-dependent control. In cycle-to-cycle control, previous data are used to predict future trends and take appropriate corrective actions. The cyclic, dynamic, and unsteady state nature of the injection-molding process is discussed with respect to the conventional proportional-integral (PI) and proportional-integral-derivative (PID) controllers as well as the more advanced control schemes such as self-tuning control, optimal control, and statistical process control. (Edited author abstract) 87 refs.

**079774 DYNAMICS OF PEAK CAVITY PRESSURE IN INJECTION MOLDING.** The modification of the injection-molding machine, incorporating additional filters, an accumulator, and a servovalve, was shown to reduce the peak cavity pressure variations, inasmuch as the variations using the microprocessor system were random in comparison to the variations using

the normal mode of operation, which exhibited nonstationarity and autoregressive behavior. If the peak hydraulic pressure could be randomized, then the peak cavity pressure variations also would be random. No closed-loop control would be needed to control the peak cavity pressure. (Author abstract) 8 refs.

**079775 COMPUTER INTEGRATED MATERIALS PROCESSING (CIMP) (NEW DESIGN ANALYSIS AND SIMULATION CAPABILITIES FOR INJECTION MOULDED PARTS).** This article describes the advantages of using an interactive software package based on solid modeling for the design and simulation of injection molded parts. An expert system assists the user in the decision making process at any time during the development of the part. With the help of interactive graphic menus, supported by a flexible database, the process begins with the solid representation of the part. Interactively, the program allows the user to analyse the filling and the cooling phases as well as the actual behavior of the mold in order to optimize the design and manufacturing parameters. The supporting database has been developed by taking into account the design and manufacturing guidelines, material characteristics and information on tooling and polymer processing. Then a complete optimization can be performed during the finite element analysis which is based on the information obtained from the results of the process simulation. (Author abstract) 4 refs.

**079776 MAKING METAL PARTS IN A PLASTICS MOLDING SHOP.** An innovative and cost-efficient manufacturing process using a resin binder and plastics processing methods - in this case, injection molding - produces sintered metal parts superior to those made by traditional powder metallurgy. The molded parts hardly need secondary machining, other than occasional touch-ups at gates. Metal injection molding (MIM) parts are finding applications in such areas as aerospace, biomedical/orthodontal, and computers. Again, the rewards of using the MIM process are many: parts can be made from metals difficult to machine, parts can be pre-alloyed, and more. Now new classes of metal/binder formulations have become available and optimal conditions for injection molding have been identified.

**079783 OPTIMAL ANTICIPATORY CONTROL OF RAM VELOCITY IN INJECTION MOLDING.** This paper discusses a computer control system for ram velocity of an injection molding machine using optimal state feedback based on the linear quadratic control theory. A new approach for the selection of appropriate weighting matrices is presented in this context. The simulation results reveal that the optimal controller has improved performance over the conventional PID controller presently used, having faster speed of response, significantly better tracking performance, and better noise filtering properties. The execution speed and the core storage requirements would allow implementation even on a small online computer. (Author abstract) 6 refs.

Pandelidis, I.O. (Univ of Maryland, College Park, MD, USA); Agrawal, A.R. *Polym Eng Sci* v 28 n 3 Mid-Feb 1988 p 147-156.

**079784 OBSERVERS FOR OPTIMAL ANTICIPATORY CONTROL OF RAM VELOCITY IN INJECTION MOLDING.** The application of optimal anticipatory control assumes that the entire state is available for feedback. However, in the case of injection molding this assumption is violated due to economic considerations. For that purpose, this paper discusses the effectiveness of optimal anticipatory control using estimates of the states obtained from a dynamic system, called observer. State estimation is essential to optimal control techniques since in general the states are used in some form of feedback and the number of measurable states is usually much less than the actual number of state variables, limited by the availability of cheap and rugged sensors and the ease of installation. Furthermore the measurements from the existing sensors may be corrupted by significance noise. In the present paper both the stochastic and the deterministic cases are investigated for application to optimal control of ram velocity in injection molding. (Author abstract) 2

**079786 STUDY OF THE WELD LINE IN INJECTION MOULDINGS.** The different condition of the material in weld line regions may be attributed to orientation resulting from flow processes and, in the case of partially crystalline materials, to different crystallization behaviour because of molecular orientation and the considerable degree of melt cooling which has already taken place before the flow fronts meet. In addition, there are two other influencing factors relevant to moulding quality: the first is the notch effect of the weld line which as the moulding cools shrinks to form a sharp furrow; the second is the concentration of inhomogeneities in the weld line which are pushed ahead of the melt front during the mould filling operation. These inhomogeneities may be abraded particles and impurities or mould release agents.

Wendt, U. *Kunstst Ger Plast* v 78 n 2 Feb 1988 p 10-11.

**079787 COMPUTER AIDED APPLICATIONS TO INJECTION MOLDING: TRANSFINITE/FINITE ELEMENT THERMAL/STRESS RESPONSE FORMULATIONS.** The paper describes two different computational approaches for simulating the effects due to temperature variations and therein the associated thermally induced stresses and warpage with emphasis on computer aided engineering applications to 'plastic' components. One approach is the conventional finite element approach, and the other is termed as the transfinite element approach. The development of unified thermal/stress formulations for each of the aforementioned approaches is described for applications to injection molded plastic parts. Results of both computational formulations are in excellent agreement for predicting the thermal response and unified thermal/stress response and agree qualitatively with previous studies. For this study, it is found that the transfinite element formulations are computationally more efficient although the conventional formulations can still be effectively used. (Edited author abstract) 11 refs.

**079788 NEW INJECTION MOLDING TECHNOLOGY USING FUSIBLE TIN ALLOYS.** In the plastics industry, tin is being used as an alloying agent for the production of a new generation of alloys for the production of plastics, automotive accessories and components. New techniques have enabled industrial plastics components - with complex internal geometry - to be mass-produced on a route basis. This has been achieved by using mechanical and thermal properties of the alloys, plus novel casting techniques developed by Fry's Metals.

Low melting point alloy cores are made, the plastics component formed and the case is melted out in an integrated machine cycle. Fry's Multi-purpose Liquid Metal Dispenser overcomes the problems of slow production rates, metal residues, oxidation and metal loss associated with previous methods.

Pascoe, Graham (Cookson Group plc, London, Engl). *Tin Its Uses* n 153 1987 p 14-15.

**079789 STUDY OF INJECTION MOLDING. (3RD REPORT, PARTIAL THERMAL SHRINKAGE IN THE BOSS STRUCTURES).** In the injection molding process, when the method resin solidified by the cooling effect from the die, non-equivalence of the cooling history caused the sink-mark growth in the resin, near boss structures. In this study, relations between Sink-Mark depth in the boss structure and some molding parameters are experimentally evaluated, and especially the effect of the forming pin is considered. Also, cooling simulation by thermal analysis is done. In considering the P-V-T characteristics and cooling history of the resin, the experimental results are quantitatively explained. (Author abstract) In Japanese. 7 refs.

**079792 QUALITAETSSTIEGERUNG BEIM SPRITZGIESSEN ALS AUFGABE DES PLASTIFIZIERSYSTEMS. [Role of the Plasticizing Systems in Improving Injection Molding Quality].** To an ever increasing degree the market requires parts of extremely high quality. In addition, these parts must be produced economically because of the intense competition. The quality level demanded results from the high performance expectations of engineered plastic parts, higher quality standards set by purchasers and expanded quality awareness on the part of end users. The factors affecting the molded part quality are presented. From a processing standpoint, requirements to be fulfilled by the plasticizing process are described. The measures available in the melting and homogenization process in the plasticizing system to optimize melt quality are discussed. 25 refs. In German.

Buerkle, Erwin (Krauss-Maffei Kunststofftechnik, Munich, West Ger). *Kunstst Ger Plast* v 78 n 4 Apr 1988 p 289-295.

**079793 EIN UEBERBLICK AM BEISPIEL EINES STOSSFAENGERWERKZEUGES. [Programs for the Rheological Design of Injection Moulded Parts].** The bumper has been taken as an example since it requires

highly comprehensive observation in order to achieve a good and precise result. With a large number of other mouldings or moulds, it will doubtless frequently be sufficient to compile a flow pattern and/or conduct an analytical calculation. The outlay required to ensure that the task is solved correctly must, however, be worked out on a case-by-case basis. The approach described makes it possible to predict the filling behaviour of injection moulds and thus introduce a greater degree of reliability into mould design. This alone, however, will not guarantee absolutely perfect results when the first sample mouldings are produced. (Edited author abstract). 6 Refs. In German.

Malz, Juergen. *Plastverarbeiter* v 39 n 5 May 1988 p 16-26.

**079794 BDE-SYSTEME DER SPRITZGIESSMASCHINEN-HERSTELLER. [Production Data Acquisition (Part 3)].** *Plastverarbeiter* is publishing a series of reports on the results of a study conducted by the Institut fuer Kunststoffverarbeitung (IKV) at the end of 1987 on 'Production Data Acquisition in Injection Moulding Shops'. The part, Part 3, presents a market analysis of production data acquisition systems supplied by eight injection moulding machinery manufacturers. Since this market analysis is based solely on data supplied without any obligation and on informatory talks with staff from different departments at the system supplier companies, the authors are unable to assume any liability for the accuracy of the information presented. This applies particularly to informative on the scope and cost of the systems, especially since the systems are subject to modification on account of constant further developments. Almost all the manufacturers have adopted a central computer concept for production data acquisition and automation of the machine environment. (Edited author abstract). 9 Refs. In German.

**079795 NON-ISOTHERMAL RADIAL FILLING OF CENTER-GATED DISC CAVITIES WITH VISCOELASTIC POLYMER MELTS.** A comprehensive two-dimensional mathematical model is developed for injection mold filling of disk-shaped cavities. The model takes into account the effects of viscoelasticity, non-isothermality, fountain flow and the shape of the flow front. A new variable slip boundary condition is used to avoid discontinuities in the flow structure and to maintain the shape of the flow front. The predictive capabilities of the model include radial and transverse velocities, pressures, temperatures, shear stresses, and the first- and second-normal stress differences throughout the filling stage. Results of the simulations, obtained using the White-Metzner (viscoelastic) and the generalized Power-law (inelastic) constitutive equations, indicate that the viscoelasticity does not significantly affect the velocity and temperature profiles; however, its effect on the stress distributions is substantial. (Author abstract). 50 Refs.

## Inspection

**079798 RELIABLE PROCESS CONTROL FOR FLEXIBLE INJECTION MOULDING PRODUCTION SYSTEMS.** A reproducible process control system is highly important in the injection molding process. It is possible to determine the machine settings in advance by means of process simulation using machine, mold and material data, and then to check these on the machine. By correlating these settings with measured product properties it is then possible to conduct an analysis of processability and build indirect product-adaptable control circuits. (Author abstract)

Steinbichler, G.; Lampl, A. *IPE Int Ind Prod Eng* v 11 n 2 Jul 1987 p 68-70, 72.

## Ion Implantation

**079799 CHARACTERISTICS OF CR-39 DOPED WITH CHLORINATED COMPOUNDS.** Characteristics of CR-39 plastic containing chlorinated compounds such as HCB and DCD have been studied using relativistic heavy ions from the LBL Bevalac. These results are compared with those of pure CR-39, focusing in particular on etching properties and on whether a penetrating etch hole is produced along each particle path by a long duration etch. The relation between the reduced track etch rate and the etchant concentration for CR-39 containing HCB is quite different from that of pure CR-39. Dilute etchants gives much higher track sensitivities than do more concentrated solutions in a wide range of REL. Since type HCB/DCD CR-39 loses its sensitivity in the interior of the bulk material for low REL produced by 2.1 GeV/n Ne ions, penetrating etch holes are not produced along the particle paths after a heavy etching. (Author abstract) 10 refs.

## Manufacture

**079800 MRP II - WHAT IT MEANS TO YOU.** MRP II is a total manufacturing planning system that coordinates materials requirement planning with all the other costing and scheduling functions that make up a production process. The 'recipe' of materials and processes that go into a finished product, the bill-of-materials, is the key to MRP II software - this is what the software is designed to schedule and control. The three main factors to look for when using MRP II software are: 1) A materials-tracking system that breaks down recipes and the amounts of materials in finished parts by weight, including scrap, and monitors materials inventories; 2) A production monitoring system that can track machine and tooling performance, even for specific mold cavities; 3) A job quoting system that provides accurate estimates of the cost and length of a production run. And the key to a plastics MRP II system is the complete integration of these modules. A list is presented of factors to be considered before investing in a system.

**079801 EFFECTS OF RESIDUAL STRESS ON THE MECHANICAL PROPERTIES OF GLASSY POLYMERS.** Residual stresses can have either beneficial or detrimental effects on the mechanical properties of plastics. Manufacturing processes frequently impose residual stresses on plastics. In this study, controlled thermal processes were used to impose surface compressive stresses on polycarbonate beam samples (6.4 by 12.5 by 80 mm). Resistance strain gage and photoelastic techniques were developed to measure the magnitude of these stored stresses. The compressive surface stresses were found to be between 14 MPa (2000 psi) and 31 MPa (4500 psi) and to vary with process method and cooling rate. The mean fatigue life (in bending) of the treated beam samples was found to improve by a factor of 10 over that of untreated samples. (Edited author abstract) 10 refs.

Hornberger, L.E. (Univ of Utah, Salt Lake City, UT, USA); Devries, K.L. *Polym Eng Sci* v 27 n 19 Oct 1987 1473-1478.

**079802 TORSIONAL PROPERTIES AND DURABILITY OF SUPER ENGINEERING PLASTICS.** High performance engineering plastics (named 'Super Engineering Plastics'; SEP in Japan) have been considered as practical materials of great promise for not only thermal use but also mechanical use. But data on their torsional performance and endurance are particularly scanty. We studied five kinds of SEP: three liquid crystalline polymers, PPS, PES, and PEEK, and three popular engineering plastics, i.e. polyamide and polyacetal for comparison. The properties determined include thermal, torsional, bending, fatigue, and solvent stress cracking properties. 2 refs. In Japanese.

**079803 DYNAMIC MECHANICAL BEHAVIOR OF POLYMERS CONTAINING CARBON BLACK.** The dynamic mechanical behavior of carbon black filled polymers of styrene and butyl methacrylate was examined

at low strain amplitude and frequency in order to minimize destruction of the composite structure and elucidate the basis of yield and plasticization observed in steady shear. Yield behavior was observed most readily for the low molecular weight polystyrene. Limiting moduli for filled polystyrenes were independent of temperature, whereas, for polybutyl methacrylate, they were sensitive to temperature. It is suggested that an independent network of carbon black is strongest in the low molecular weight polystyrene and weakest in poly(butyl methacrylate). (Edited author abstract). 31 Refs.

## Medical Applications

**079804 TOMORROW'S PLASTICS MAY ADD YEARS TO YOUR LIFE.** Plastics have had a dramatic impact on the health care industry in the past 50 years, and the new century holds even more promise. Plastics have simplified patient care, reduced contamination, made possible new prostheses and treatment techniques, and cut medical costs. Three billion pounds of plastic will be used in the medical market by the year 2000. Resin use for monitors and analyzers housings will grow at more than 15 percent/year in the next decade. Improved plastics will make possible artificial kidneys, urinary bladders, and artificial skin. New thermoplastic elastomers will make possible better artificial heart implants.

Lodge, Charles (Plastics World, Newton, MA, USA). *Plast World* v 45 n 10 Sep 1987 5p.

**079805 TECHNICAL PAPERS - REGIONAL TECHNICAL CONFERENCE: PLASTICS FOR TOMORROW'S MEDICAL NEEDS.** This conference proceedings of 21 papers is divided into four sessions with the following subjects of interests: biocompatibility, sterilization, property assessment, and material development. Some topics discussed by the 21 papers are here cited as examples: high performance polyurethane elastomers in artificial hearts; a progress report; hydromer coatings for medical devices; wanted: radiation stable plastics; sterilization resistance of TPX; microtexturing of plastics for implantation; selection criteria for materials in medical applications; design considerations in the in vitro testing of cardiovascular prosthesis; predicting long-term performance from short-term testing; the versatility of polyurethanes; polycarbonate and medical devices - a lasting relationship; silicone RTV adhesives; and new transparent and low tensile set biocompatible thermoplastic elastomer based on polysiloxane modified block copolymers. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10905 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Metallizing

**079806 VACUUM METALIZING: NOW MORE THAN JUST A DECORATING PROCESS.** For the production of floppy discs, thin-film magnetic cobalt-nickel films just 70 to 100 microns thick are applied on thin polyester substrates. Microprocessor-controlled sputter-type roll coating systems guarantee optimal layer-thickness uniformity at commercial rates, thus insuring product quality and cost-effectiveness. Sputtering techniques using reactive gases in combination with metal targets (which are essential to uniform deposition of the coating) are also being used to produce transparent conductive films. Multilayer sputtering technology is being applied to produce transparent antireflective coatings and thermal radiation blankets for aircraft and aerospace applications. In addition, metallizing is being combined with other vacuum coating technology to upgrade plastic quality. Heavier sputtered coatings of copper and gold are

used to produce metal coated plastics film and sheet for the etched printed circuit board, another growth market. Progress in equipment design and application are also discussed.

**079807 WATER ABSORPTION OF RESINS AND COMPOSITES: III. WATER DISTRIBUTION AS INDICATED BY CAPACITANCE MEASUREMENT.** Glass fiber reinforced epoxy pultrusions were made with a range of fiber volume fractions. They were immersed in water at temperatures in the range 23 to 100°C until saturated, and their dielectric properties measured. Tests on the saturated resins themselves indicated that 60 to 75% of the water was concentrated in disk-shaped regions. The remainder of the water was probably molecularly dispersed; the proportion of this phase depended on the presence of polar groups in the polymer. In the case of the composites, the water provided conducting paths, probably caused by the interconnection of regions of water concentration at the fiber-matrix interface by the water 'disks' that exist in the resin. Dielectric tests appear thus to be a potent tool for providing information about the morphology of resins and composites containing water. (Edited author abstract) 10 refs.

## Mold Release Agents

**079808 SELECTIVE FATTY CHEMICALS AS MOLD-RELEASE AGENTS.** A new test measures the effectiveness of various non-metallic fatty chemicals as internal mold-release agents for several resins. Test results suggest an optimal mold-release additive for each resin. The resins tested were ABS, acetal, polybutylene terephthalate, polypropylene, HDPE, and LLDPE. (Author abstract)

**079811 CUSTOM-MOLDING START-UP FOUNDED ON CAE.** Interplas, Ltd., Menomonee Falls, Wis., started business early in 1987, with the intention of concentrating on high-performance jobs involving engineering resins and difficult molding requirements. Interplas has just two 60-ton presses, but they are equipped with a quick-mold-change system and microcomputer controls that can be programmed remotely. Unlike most processors, the owners also installed a CAD system. At Interplas, plastic part and mold design are not considered separate entities.

Anon. *Plast Technol* v 34 n 1 Jan 1988 p 29, 31, 33.

**079812 CASE FOR ALL-STAINLESS MOLDS.** Stainless molds have made possible many of today's most demanding applications, including those where product function requires the 'ultimate' surface finish. Examples include audio CDs and video discs, optical-quality lenses, close-tolerance camera parts, intra-ocular lens implants, and optically clear medical parts. In recent times, all-stainless molds have been used in a growing number of such applications: surface-critical discs, video products, optical appliances, medical devices.

Anon (Uddeholm Corp). *Plast Technol* v 34 n 1 Jan 1988 p 63-65.

**079813 SELECTING PLASTIC PARTS FOR COMPUTER-AIDED ENGINEERING ANALYSIS.** CAE analysis can provide critical information for optimizing design and processing parameters to insure the successful molding of plastic parts. It is a cost effective alternative to the conventional 'cut and dry' methods. Since it is neither practical nor economical to conduct an analysis for every plastic part, a procedure has been developed to screen plastic parts. This screening process is intended to provide a framework which can be further developed by individual users into a customized selection process.

Litman, Alan M. (Xerox Corp, Webster, NY, USA); Chathampally, Mohan R.; Fowler, Norman E. *Polym Plast Technol Eng* v 26 n 3-4 Sep-Dec 1987 p 333-345.

**079814 NEW APPROACH TO LOW THERMAL INERTIA MOLDING.** This paper investigates a new approach to the implementation of the LTIM (Low Thermal Inertia Molding) concept. Thermoelectric modules are used to form the mold cavity. By controlling the magnitude and polarity of the power input to these modules, the mold cavity surface can be heated and cooled rapidly. An experimental simulation of the mold cavity requirements is conducted on the thermoelectric modules to test the feasibility of using these modules to form the mold cavity. To obtain precise temperature control of the mold cavity surface, a special temperature control system is designed and custom built. Experimental results show that a temperature response of 4 s is obtained for heating the mold cavity surface from 40 to 125°C with a power density of 58 W/in.<sup>2</sup>. The module endured more than 135,000 thermal cycles from 40 to 125°C with a heating time of 10 s and a power density of 37 W/in.<sup>2</sup>. The compressive strength of the modules was only 500 psi. 2 refs.

**079815 STUDY OF ISOTHERMAL SIMPLE SHEAR FLOW FOLLOWED BY NONISOTHERMAL STRESS RELAXATION IN A LOW THERMAL INERTIA MOLDING.** In order to analyze the stress relaxation in the molded part, a rheological constitutive equation that can characterize the nonlinear viscoelastic flow behavior of the polymer melt must be used. M.H. Wagner's integral-type constitutive equation is utilized in predicting the stress relaxation from the instant the mold is filled isothermally by fully developed simple shear flow.

Study of stress relaxation showed that the flow-induced stress can be relaxed on the order of a second. When the relaxation takes place before the vitrification, a part with the minimum residual stress can be molded. Because of the viscoelastic nature of the polymer melt, the more strain the melt undergoes within the longest relaxation time period, the faster it will relax. Hence the cavity should be filled as rapidly as possible for molecular relaxation and for decreasing total cycle time. 13 refs.

Kim, Byung H. (Univ of Massachusetts at Amherst, Amherst, MA, USA); Suh, Nam P. *Polym Plast Technol Eng* v 26 n 1 Mar 1987 p 23-44.

**079816 'EXPERT' CIM SYSTEM INTEGRATES INJECTION AND BLOW MOLDING.** Complete plantwide monitoring and control networks, with built-in SPC and SQC functions based on new 'expert system' software, are now available for injection and blow molding. This system incorporates previous releases of Hunkar's CNC-1000 total machine controller, DAT data-acquisition terminal, on-line SPC analysis software, and factory network data highway. The latest enhancements include: expert software for more sophisticated injection and blow molding statistical process and quality control; cell control that integrates the molding machine with auxiliaries; and a new and more powerful central plant control/monitoring station.

Anon. *Plast Technol* v 34 n 4 Apr 1988 p 15, 17, 19.

**079817 BLUEPRINT FOR CIM IN PLASTICS MOLDING.** The CIM plan allows the molder to use molding and auxiliary equipment of his choice and does not tie him to any one manufacturer. It employs technologies that can be retrofitted to existing molding and auxiliary equipment. While the injection molding process is taken as the model for this conceptual presentation, the plan is also being implemented in blow molding and transfer molding for semiconductor encapsulation. The elements are: process control with statistical process control; automated quality control with statistical quality control; computer-aided response program; computer-aided equipment maintenance program; production control with qualified MIS data. The physical components include: central computer; machine network; local area network; remote data-display network; data collection terminals; data-bases.

**079818 DIMENSIONLESS CURVES FOR PRESSURE OF A HEATED DIE SLOT.** The flow of polymer melts in dies commonly involves heat transfer and temperature differences between the melt and the die lips. This results from heat conduction and viscous heat generation. The melt may also enter the die at a different temperature than the die lips, resulting in temperature changes in the melt. The melt viscosity is normally also very dependent upon temperature and shear, and it will thus vary throughout the melt. The purpose of this analysis is to present a mathematical solution for the pressure of developing flow of polymers in heated dies. A unique set of dimensionless curves is devised which can be easily used for die pressure calculations for a large range of flow conditions and melt properties. 5 refs.

**079819 GUIDE TO MOULD MAINTENANCE.** The article discusses the common causes and cures of problems with expensive and vital mould tools, plastic injection mould tools. The advantages of maintenance are pointed out. Some of the problems covered are worn or seized pins

and ejectors, corrosion and furring, misalignment and damaged seatings.

Atkinson, Bob (DME, Engl). *Prod Eng (London)* v 67 n 3 Mar 1988 p 19-20.

**079820 COPING WITH THE WARPED PERSONALITY OF MOLDED PLASTICS.** Because plastics shrink locally rather than globally, their patterns of warpage can be extremely complex. With the aid of software, designers can now predict the shrinkage at each area. They can then modify the part and the mold to minimize both warpage and residual stress. Engineering software modules are now available that model the molding and cooling processes and allow designers to predict shrinkage at each area of the part before a prototype is made. (Edited author abstract)

**079821 UK COMPANIES HELP THEMSELVES TO EXPORTS.** The author reports on how three subcontract moldmakers are exploiting technology to give them a competitive edge when the EEC trading barriers come down in 1992. All three companies are relying heavily on the use of numerically controlled machine tools using programs generated from CAD data and have invested heavily in leading-edge CAD/CAM technology for the production of complex molding dies for plastics injection molding.

Anon. *Mach Prod Eng* v 146 n 3740 Jun 3 1988 4p.

**079822 HOW YOU CAN AFFORD A QUICK-MOLD-CHANGE SYSTEM.** With a modest capital investment in a manually operated or semi-automatic quick-mold-change system, injection molders reportedly can achieve a major degree of the increased manufacturing flexibility, efficiency, and productivity provided by more technologically advanced (and expensive) fully automated QMC systems. The basic philosophy of QMC is to minimize machine downtime by carrying out the physical process of changing a mold and bringing the machine back into production as rapidly and efficiently as possible. This involves standardization of the mold/machine or automating the different steps necessary in changing a mold. Five key elements of QMC systems are examined with emphasis given to how each element might be affordably adopted. These five elements include the following: Mold handling in and around the machine. Mold locating in the machine. Mold clamping. Utility connections. Materials and color changes.

**079823 STRESS OPTICAL STUDIES OF DRAWN POLY(ETHYLENE METHYL TEREPHTHALATE).** Oriented tapes of poly(ethylene methyl terephthalate) (PEMT) and a 60/40 copolymer of PEMT and poly(ethylene terephthalate) (PET) have been prepared by drawing at different temperatures above and below the glass transition temperatures. It was established that in all cases the drawn samples showed no detectable crystallinity. The development of molecular orientation was characterized by birefringence and from the magnitude of the shrinkage force observed on heating above  $T_g$ . The results can be considered in terms of the deformation of a molecular network, without introducing complications due to crystallinity, and this was shown to provide a good first-order explanation for the data on drawing above  $T_g$ . Drawing below  $T_g$ , on the other hand, is better modelled by the pseudo-affine deformation scheme. (Author abstract) 35 refs.

**079827 PLASTICS PROPERTIES FOR DATA BANK AND DESIGN: MEANINGFUL - COMPARABLE - ECONOMICAL TO DETERMINE.** Observations show that the three basic requirements in respect of plastics properties are, at least from the viewpoint of the designer, at present only inadequately fulfilled. An improvement in the situation can only be achieved by first of all attempting step-by-step to meet the basic requirements for characteristic values permitting a comparison of

different products and preliminary selection of products for specific applications. For this purpose it is necessary to drastically reduce the number of test methods as well as the types of specimen and to standardize the preparation of the specimens and the performance of the tests. Basic values determined by these methods are specifically suited for filing in data banks. 4 refs.

**079828 ADHEESIO- JA BARRIERMUOVIT.** [Adhesion and Barrier Plastics]. Neste Oy has been active in the development of adhesion and barrier plastics for several years. The aim has been to develop a complete line of materials, especially for gas-tight food packaging applications with low permeability to oxygen, carbon dioxide etc. At least three layers are needed for workable packaging solutions: a barrier layer, a heat-sealing layer and an adhesion layer between the barrier and heat-sealing layers. In most cases five layers are needed, to achieve a balanced structure for packages, resistant to curling and moisture. The barrier and heat-sealing layers are non-compatible because barrier materials contain polar groups and heat-sealing materials are non-polar. (Edited author abstract) In Finnish.

**079829 PROBLEMS WITH PLASTICS DURABILITY IN NEW ZEALAND BUILDINGS.** The overall level of problems is low, but individual problems have been quite large. Several case histories are discussed to illustrate: the consequences of the New Zealand environment for plastics; the influence of material specification on plastics durability; the influence of design on plastics durability; and the prediction of plastics durability. There are two main conclusions from the consideration of plastics problems. The first is that there is a need for better education of building designers and specifiers about plastics properties and their implications for durability. The second is that better means of predicting plastics durability are needed. (Edited author abstract) 13 refs.

**079831 MECHANICAL PROPERTY ENHANCEMENT OF SEMICRYSTALLINE POLYMERS-A REVIEW.** Processing plastics below their melting points has been shown to be an effective way to significantly enhance the mechanical, chemical, and physical properties of semicrystalline thermoplastics. A number of techniques have been developed that are capable of producing highly oriented fibers, films and shapes. In general, these tech-

niques can be classified as drawing, extrusion, and rolling, with some very specific modifications having been made to each, that affect the performance of the process. Techniques have been developed which rely on strain induced crystallization to enhance the modulus of molded parts and extrudates from a melt. This paper constitutes a review of these techniques with emphasis on the process parameters, polymers investigated, and properties of the resulting materials. (Edited author abstract). 58 refs.

**079832 PLASTICS IN HIGH TECH INDUSTRIES BY 2001 A.D.** The author surveys the status of polymer production in India. This is followed by an assessment of the global production of plastics. Several important plastics are discussed including: nylon, polycarbonates, polyacetals, polytetrafluoroethylene, polyurethanes and, rigid urethane foams. The present status of technology is examined. Finally, research and development requirements are outlined.

## Pulverization

**079833 PULVERIZING OF PLASTIC SCRAP SOLVES QUALITY PROBLEMS.** The design and applications of impact disc pulverizers are discussed. Essential differences from conventional pulverizing equipment are in the design of the grinding chamber. The impact pulverizer has a compact low-volume grinding chamber which ensures that only the quantity of material which is actually subjected to the size reduction process is present in the machine. This design prevents efficiency loss which otherwise arises from material being unnecessarily hurled around the grinding chamber. This unnecessary recirculation of material not only consumes much energy but also causes unnecessary overheating of the material.

**079834 PYROLYSIS STUDIES OF FLAME RETARDED PLASTIC SYSTEMS.** Two pyrolysis experiments have been utilized to investigate reactions pertinent to flame retardant behavior. First, a mass spectrometric evolved gas analysis technique has been used to study the influence of the flame retardant decabromodiphenyl oxide (DBDPO) and the synergists antimony oxide and zinc borate on the activation energy for monomer (i.e., fuel) evolution from polystyrene composites. Second, the extremely fast scan capability of the time-of-flight mass spectrometer has been utilized to monitor HCl and benzene evolution from various poly(vinyl chloride) (PVC) composites subjected to a very large and rapid temperature rise due to pulsed laser heating. It is found that a decrease in the smoke density value can be associated with an increase in benzene evolution (Edited author abstract) 22 refs.

## Radiation Damage

**079835 SHELF LIFE PREDICTION OF RADIATION STERILIZED POLYMERIC MATERIALS.** The functional properties of many polymers employed in

medical disposables are unaffected by sterilizing doses of ionizing radiation. However, some materials (PVC, polypropylene, cellulose, etc.) undergo undesirable changes which continue to occur for the shelf life of the product. In many cases, conventional accelerated aging techniques do not accurately predict the real time properties of the materials. As real time aging is not generally practical, it has become necessary to develop accelerated aging techniques which can predict the functional properties of a material for the shelf life of the product. This presentation addresses issues involved in developing these tests. Real time physical property data is compared to data generated by various acceleration methods. (Author abstract) 6 refs.

**079837 CHEMICAL AND ELECTROCHEMICAL REGISTRATION OF PROTONS IN CR-39 - IMPLICATIONS FOR NEUTRON DOSIMETRY.** In this paper we describe, first, the response of the chemically etched CR-39 detector to protons as a function of their energy. To do this we have irradiated the CR-39 polymeric detector with monoenergetic protons (from 0.6 to 6 MeV), and etched it chemically in 6M NaOH at 70°C. We find that normally-incident protons, in the whole energy range studied, are registrable in CR-39 when etched chemically. We then proceed to determine the track-to-bulk etch-rates ratio  $V_T/V_B$  as a function of proton energy and 'REL 350'. From  $V_T/V_B$  measurements we calculate the critical angle for CR-39 as a function of proton energy. Finally, we study the registration of protons by electrochemical etching, and then extend our studies to predict the best radiator-detector assembly which would provide a nearly flat dose-equivalent response for neutrons (which produce tracks chiefly through recoil protons) over the neutron energy range of approx. 0.1 to 19 MeV. (Author abstract) 16 refs.

**079838 METHOD FOR MONITORING THE COLLAPSE OF PLASTIC SECTIONS AS A FUNCTION OF ELECTRON DOSE.** We present a method for monitoring the collapse of plastic sections when irradiated in the electron microscope. The two surfaces of the section are separately coated with colloidal gold particles. The section is then tilted to an angle of 45° in the microscope and a series of micrographs recorded, corresponding to increasing total electron dose. The collapse of the specimen normal to the plane of the section causes a relative movement in the image of the two sets of particles marking the two surfaces. By measuring the positions of a few gold particles on each side of the section in each exposure of the series, the collapse and also the in-plane shrinkage can be computed. The sections exhibit a rapid initial collapse, followed by a much slower phase of thinning. These effects should be taken into account when producing quantitative three-dimensional maps from tilt series of sectioned material. (Author abstract) 17 refs.

**079840 SURFACE MODIFICATIONS TO MINIMIZE THE ELECTROSTATIC CHARGING OF KAPTON IN THE SPACE ENVIRONMENT.** The electrostatic charging of Kapton under electron irradiation is reduced by coating it with a dispersion of indium oxide in a soluble polyimide. The proportion of oxide in the coating and its thickness are chosen to give an optimum balance between the surface resistivity and the thermo-optical properties ( $\alpha_s/\epsilon$ ) of the film. Coatings having a resistivity  $<10^7 \Omega/\text{square}$  exhibited surface voltages below 250 V when irradiated with 30 keV electrons. Implanting Kapton with ions derived from  $N_2$ ,  $H_2$  or  $CH_4$  plasmas also gave low surface resistivities and reduced its susceptibility to electrostatic charging. Hydrogen ions were the most effective, but caused greater changes in  $\alpha_s/\epsilon$  than the ions of the other gases. (Author abstract) 10 refs.

**079841 ANALYSIS OF REACTION INJECTION MOLDING PROCESS OF POLYURETHANE-UNSATURATED POLYESTER BLENDS. PART I: COMPUTER SIMULATION.** A computer simulation model was developed to analyze the reaction injection molding (RIM) process of polyurethane and unsaturated polyester blends. The reaction kinetics and viscosity functions of each component were obtained through actual experiments, and a mathematical scheme for numerical calculation was set up in cylindrical coordinates to predict the temperature and conversion profiles within a disc-type mold. The temperature change calculated from the simulation was compared with the temperature rise measured in actual RIM experiments. The effects of the feed temperature, wall temperature, and catalyst levels on the maximum exothermic temperature and the demolding time were evaluated in a search for the optimum processing conditions. (Author abstract) 24 refs.

**079842 ANALYSIS OF REACTION INJECTION MOLDING PROCESS OF POLYURETHANE-UNSATURATED POLYESTER BLENDS. PART II: MECHANICAL PROPERTIES.** The mechanical properties of polyurethane-unsaturated polyester interpenetrating polymer networks (IPNs) that were prepared by reaction injection molding (RIM) process were measured with variations in composition, cross-link density, and relative reaction rate. From dynamic mechanical analysis (DMA), it was found that the two component polymers had a good compatibility over the whole composition range. For higher cross-link density, the compatibility was enhanced and the mechanical properties were improved. When the reaction rates of the components were different, some

extent of phase separation was found in DMA and the properties were affected adversely. (Edited author abstract) 17 refs.

Kim, J.H. (Korea Advanced Inst of Science & Technology, Seoul, South Korea); Kim, S.C. *Polym Eng Sci* v 27 n 16 Mid-Sep 1987 p 1252-1257.

**079843 ASPECTS OF THE DESIGN OF RIM PLANTS FOR THE FUTURE.** The use of plastic materials for the production of automotive body parts has been steadily increasing over the years. Weight saving, corrosion resistance, sound and heat insulation and improved impact resistance are some of the reasons behind this growth. The most utilized material for these applications has been polyurethane, processed by reaction injection molding. The use of self-releasing systems has given the processor the opportunity to improve productivity by eliminating the use of release agent and, thus, the build up of release agent. The RIM process will greatly improve its competitive position against injection molding by continued development of new raw-material systems and improved processing methods. Success is in large part based on the good cooperation between raw-material suppliers, equipment manufacturers and processors. Increased clamping forces with more rigid tool-carriers will result in better molded parts. 1 ref.

Ruehmann, H.; Schaper, H. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 8-10.

**079844 RIM STAGES A COMEBACK IN PROCESSING PRODUCTIVITY.** Faster-cycling and more versatile RIM materials are the basis for a new generation of bigger, faster clamps, metering machines, and auxiliaries designed to handle large automotive parts more productively. Specifically, the advent of polyurea RIM materials - with shot times under 1 sec. and cure times of less than 20 sec. - has made it possible to cut overall reaction injection molding cycle times to well below the semi-official 1-min. cycle requirement established for automotive parts production. Translating such faster cure speeds into production-line reality, RIM machines now are capable of making, for instance, 4x6 ft., 18-lb. Class-A surface automotive body panels in consistent 40-sec. cycles.

Sneller, Joseph A. *Mod Plast* v 65 n 3 Mar 1988 p 81-83, 85.

**079845 REACTION KINETICS OF A POLYUREA REACTION INJECTION MOLDING SYSTEM.** Polyureas have the potential for improving reaction injection molding (RIM) productivity through shorter demold times and elimination of external mold release agents and post-cure. Kinetics of urea formation are necessary for process modeling of polyurea RIM systems. Adiabatic temperature rise measurements were used to monitor the extent of reaction of an aliphatic diamine and an aromatic diamine reacting competitively with a single diisocyanate. The aliphatic diamine reacted much faster; essentially complete polymerization occurred in the RIM mixhead. A similar three-component system was studied in dimethylacetamide and diethylene glycol dimethyl ether, and the sequential nature of the two competing reactions was confirmed. The RIM polymerization of the aromatic diamine, 3,5 diethyltoluene (2,4 and 2,6) diamine and 4,4'-diphenylmethane diisocyanate was studied using an unreactive polyether as the solvent. The exotherms could be fit with a third order model. (Edited author abstract) 21 refs.

**079846 REACTION INJECTION MOLDING OF POLYUREAS I. KINETICS STUDY.** The experimental results and mathematical modeling of processing of polyureas are covered. The experimental part includes the applications of solution polymerization to study the reaction kinetics of polyureas. The theoretical part in-

cludes a kinetic and heat transfer model that can apply solution polymerization data to predict the bulk polymerization of polyurea in the reaction injection molding process. (Edited author abstract). 17 Refs.

Hsu, T.J. (Ohio State Univ, Columbus, OH, USA); Lee, L.J. *Polym Eng Sci* v 28 n 15 mid-august 1988 p 955-963.

**079847 RIM, STIM AND RTM: UP AND COMING CHALLENGERS.** An overview of the latest develops in RIM materials and machinery include: E-coat thermal resistance, DOI and class A surface; mold release; new chain extenders; mold temperature; alternative isocyanates; new fillers; cycle time and automation; larger machinery. Newer possibilities for RIM materials including SRIM materials are enumerated. The trend in the auto industry toward lower production volumes and quick model changes has thrown the spotlight on resin transfer molding (RTM), which offers the ability to make large, complex parts, with very low tooling costs. The main obstacles RTM must overcome are exceedingly high cycle times and the difficulty of obtaining a Class A surface in a low-temperature, low-pressure process.

**Recycling** See Also PACKAGING MATERIALS—Plastics; POLYETHYLENES—High Density.

**079848 EFFECT OF RECYCLE ON PROPERTIES AND PROFITS: ALGORITHMS.** In many plastics processes, nonvirgin materials make up relatively small percentages of materials added to the main processing stream. In thermoforming, however, as much as half the material that passes through the extrusion and thermoforming process chain is 'nonproduct' web. Economics usually dictate that this material must be reprocessed. Materials that experience high levels of shear and/or temperature usually exhibit measurable and significant property loss. This means that the mixture of materials fed to the process has properties somewhat less than those of the virgin resin. This paper presents algorithms for determining final product properties, given single-pass property loss and fraction of recycle in the resin mixture going to the process. (Edited author abstract) 4 refs.

**079849 MORE PLASTICS USE MEANS MORE WASTE, WHICH MEANS...** Plastics represented 11.5% of the waste stream in 1986, according to a 1986 study done by Franklin Associates, Prairie Village, Kan. That compares to 27.1% for glass and 47.8% for paper. Legislators, environmentalists, and others, noting that the increased use of plastics means more non-degradable wastes, are pressuring the plastics industry to do something now. One solution may be a shift to more bio- and photo-degradable plastics. These materials degrade more quickly in the environment than the current widely-used plastic. Recycling, even as it is sometimes proposed as the ultimate solution for the nation's refuse disposal problem, is often proposed as another 'solution' to the problem of plastic wastes disposal. Plastics recycling is not highly successful for several reasons, but the outlook is getting better. PET, most familiarly known to consumers as the component of the soft-drink bottle, is being reclaimed at a rate of about 62,500 tons per year. When granulated, recycled PET can be sold more cheaply than virgin resins; fiberfill (stuffing) is one of its more common end-uses. These and other aspects of the subject are discussed.

Tallman, Jill W. *Waste Age* v 18 n 9 Sep 1987 p 141-142, 144, 146.

**079850 MIXED PLASTICS RECYCLING: NOT A PIPE DREAM.** Innovative firms are pioneering technologies to recycle co-mingled plastic wastes from residential and industrial sources into marketable products. This approach can provide two income streams: revenue from sale of finished products and, in some cases, from tip fees charged for this plastic 'disposal' service. Such enterprises are gaining momentum in several regions of the U.S. and

Western Europe where disposal capacity is at a premium and/or environmental pressures are prompting diversion of plastics from the waste stream. Featured in this article are three firms that lead in the development of mixed plastic recycling.

Brewer, Gretchen (Massachusetts Div of Solid Waste). *Waste Age* v 18 n 11 Nov 1987 5p between p 153 and 160.

**079851 REPROCESSING PLASTICS SCRAP.** Uniform production scrap is frequently recycled directly by plastics processors or is otherwise normally sent to reclaiming plants. Scrap from used plastics articles on the other hand requires considerably more extensive treatment before it can be converted into usable material by recycling processes. Purpose-built machinery and equipment for both categories of scrap are described and the economics of the different processes for various recycling tasks discussed. (Author abstract) In German and English.

Schalles, H. *Kunstst Ger Plast* v 77 n 11 Nov 1987 p 3-6, 1127-1133.

**079852 ECONOMIC RECYCLING OF PRODUCTION WASTE FROM PVC FILM AND SHEETING CALENDERING PLANTS.** Rational in-house upgrading of production waste is of considerable economic importance, particularly for calendaring shops that produce PVC film. Not enough attention is paid to this factor in all cases, however, despite the fact it has a considerable influence on costs. The plant concept described, which has also been built, involves a recycling system which makes optimum use of production waste employing the automatic raw material transport system that already exists and requiring minimal outlay on labour and costs. (Author abstract) 9 refs. In German and English.

Schick, J. *Kunstst Ger Plast* v 77 n 11 Nov 1987 p 7-10, 1134-1139.

**079853 FESTIGKEITSEIGENSCHAFTEN VON VERSCHMUTZTEM, WIEDERAUFBEREITETEM POLYETHYLEN. [Strength Properties of Contaminated, Reprocessed Polyethylene].** The re-use of thermo-plastics has been practised for many years. This is of considerable economic and ecological significance. What is scarcely known, however, is the extent to which contaminants influence the strength properties of a thermoplastic. Taking polyethylene as an example, the effects of specific contaminants are investigated and compared with practical experience. (Author abstract) 12 refs. In German.

Sikora, Robert (Technische Univ, Lublin, Pol); Bielinski, Marek. *Kunstst Ger Plast* v 78 n 4 Apr 1988 p 335-338.

**079854 PAIR PLAN TO PREVAIL OVER PLASTICS.** The Plastics Recycling Action Plans developed for the states of Massachusetts and Rhode Island by Recuperc, Inc. (Quebec) are described. Many parts of the plans are already being implemented in the two states. The study found that the average portion of the waste stream plastics (by weight) is 8 percent. The average American throws away 45 pounds or 1.5 cu. yds. of plastics per year. Experience in plastics recovery from the waste stream, gathered from 41 multi-material collection programs in the U.S., Canada, and Europe, was studied. The recommended strategy is summed up.

Brewer, Gretchen (Solid Waste Management, USA). *Waste Age* v 19 n 8 Aug 1988 4p.

**079855 ACTIVE RECYCLING OF PLASTICS.** Disintegration of thermoplastic particles and waste into granular matter and grains which can be directly reused is particularly important. After the method of separating plastic particles for further use, it is the most efficient recycling method for thermoplastic materials which clearly accounts for the greatest part of plastics; however, it does not preclude the application of further recycling methods based on chemical conversion which are most common with cross-linked elastomers and duroomers. As direct reprocessing constitutes an ideal, however, seldom adapted, recycling technique, research is under way at the

Plastic Engineering Institute of the Technical University of Berlin in order to identify the measures that are necessary for extensive recycling on the basis of direct reprocessing of thermoplastic materials. This paper discusses the subject in terms of materials selection and product design, properties of parts made of recycling products, recycling strategies, and others.

Kaeuffer, H. *Conserv Recycling* v 10 n 2-3 1987, Recycl of Mater, Sel Pap from the Fifth Int Recycl Congr, Berlin, West Ger, Oct 29-31 1986 p 153-167.

**079856 IMPROVING THE HOMOGENEITY AND MECHANICAL PROPERTIES OF PLASTICS WASTE CONTAMINATED BY PAPER USING A HYDROLYTIC TREATMENT.** It is the purpose of the present contribution to demonstrate the potential of a hydrolytic treatment of plastics waste contaminated with paper. Such treatment is intended to embrittle the cellulosic component so that it is easily disintegrated into small fragments in the shear field acting in normal plastics processing machinery (extrusion, injection moulding). This in turn results in significant improvement of the homogeneity of the product as reflected by its appearance, and also by its mechanical parameters. The paper illustrates the effect of hydrolysis on the mechanical parameters of injection moulded test bars produced from plastics waste obtained from two different sorting plants. 4 refs.

## Reprocessing

**079858 REPROCESSING OF PLASTICS WASTES.** In-house reutilization of sorted plastics wastes is nowadays for reasons of cost largely state of the art. On the other hand it is considerably more difficult to reprocess wastes that occur from the scrapping of used parts. The problems of separation and reprocessing are illustrated with a special case. **079860 LOW PRESSURE RHEOLOGY OF GRANULAR POWDERS USING A DRAWING PLATE TECHNIQUE.** An analysis of a drawing plate test for easily monitoring the low-pressure frictional characteris-

tics of powders is presented. The test is performed by measuring the force required to withdraw a plate from a cylindrical bed of dry powder. The characteristics of the drawing force profile are analyzed using Janssen's classical differential element approach to relate the product  $\mu K$  of powders as a function of packing of powder medium, where  $\mu$  is the coefficient of friction of the powders against the solid drawing plate, and  $K$  is Janssen's constant, an anisotropic pressure distribution factor of a powder bed. The packing arrangement, expressed as the external void fraction, due to tapping, significantly alters the  $\mu K$  value and the effective sustaining strength of a powder bed. Experimental results on spherical glass beads having mono- and bimodal size distributions, and on three different poly(vinyl chloride) [PVC] powders are discussed. (Edited author abstract) 51 refs.

**079863 SPIN COATING THIN FILMS OF PLASTIC SCINTILLATOR.** Nuclear reactions initiated by heavy-ion beams have greatly enriched the spectrum of nuclear reactions. Often these reactions are characterized by broad mass, charge, and energy distributions of the resulting fragments. The experiments must therefore be measurements with a large dynamic range of energy and either mass or charge for each of these fragments. One type of detector which has been utilized extensively is the scintillator sandwich, or phoswich. The most common type made during the last few years consists of a thin, fast plastic scintillator as the first element ( $\Delta E$ ) and a thick slow plastic scintillator as the stopping detector (E). Thin, uniform layers of plastic scintillator have been created on supporting aluminized Mylar by the use of the spin coating technique. 9 refs.

**079865 CONTROLE DES RESINES POLYESTER INSATUREES POUR SMC: TEST DE LA REACTIVITE DES MAGNESIES LORS DU MURISSEMENT DES RESINES.** [Monitoring Unsaturated Polyester Resins for SMC: Testing the Reactivity of the Magnesiums Used in the Curing of the Resins]. It is important to know and control the thickening process of unsaturated polyester resins, in order to realize prepreps with the SMC (Sheet Molding Compounds) process. Magnesium oxide MgO is the thickening agent mostly used but its reaction mechanisms are still not fully understood. The authors have characterized some magnesium oxides with various macro- and microstructures. The main reactivity parameters of MgO were established: surface aspect, size and distribution of particles, carbonation and hydration, previous impasting. It was found that an acid-base reaction seems to be a good model of the reaction's first step, which leads to a gel formation. As a consequence, an easy and quick test of acid attack is suggested for estimating the thickening power of MgO. (Edited author abstract). 14 Refs. In French.

**079868 STRESS-STRAIN PROPERTY REFERENCE POINTS FOR NON-LINEAR MATERIALS.** A graphical analysis of stress-strain data has been devised which delineates the elastic-plastic transition region giving nominal elastic and initial yield property reference points for a material. In addition an intermediate point is obtained using a tangential construction to the stress-strain curve. Possible areas of application include: design limits for lightly stressed components; measures of material toughness; hardness and damage resistance;

elastic-plastic stress analysis and adaption of design procedures to materials response changes. The materials considered are thermoplastics, a liquid-crystal polymer and polymer-bonded explosive systems. (Author abstract) 15 refs.

**079869 UNIAXIAL STRESS RELAXATION OF SOFTENED CELLULOSE (APPLICABILITY OF NONLINEAR VISCOELASTIC MODEL TO LARGE STRAIN).** Uniaxial stress relaxation of cellulose softened by heating was observed experimentally. The experiments consisted of the constant strain (single step) and the gradually stepup strain tests. The representation of stress relaxation was evaluated by the single integral nonlinear viscoelastic model up to the third order of strain. For the constant strain test, though residual stress at a certain duration after application of strain increases in proportion to strain in the range of small strain, it decreases with an increase in strain above a certain level of strain. The prediction of stress relaxation by the model with third order of strain agrees with the observed data. For the gradually stepup strain test, the variation of stress which occurs instantaneously under the change of strain is almost constant for the number of steps. Residual stress at the end of each step increases with the number of steps, and the hardening of the material appears. Additional study results are discussed. (Edited author abstract) In Japanese. 13 refs.

**079870 TEMPERATURE RISE OF FOIL STRAIN GAGES ON PLASTICS.** In strain measurements of plastics using foil strain gages, the temperature rise caused by power dissipated in the gage produces serious errors. A simple model for estimating the temperature rise is proposed, that is, a single strip representing a grid is bonded onto a half space made of plastic, and generates constant heat flux. A formula and diagram, by which the maximum value of the temperature rise can be estimated, are presented in this paper. The estimated temperature rise,  $T_{max}$ , is about 2 times as large as the measured one for actual gages bonded onto acrylic plates. The difference between both values is due to the incompleteness of the gage model and errors in the temperature measurement using a thermocouple. In spite of this incompleteness, the value of  $T_{min}$  is almost constant for the number of steps. Residual stress at the end of each step increases with the number of steps, and the hardening of the material appears. Additional study results are discussed. (Edited author abstract) In Japanese. 13 refs.  $a_c$  can still be used to estimate the temperature rise of the actual gages. This value is more useful than the power density which is often used as a parameter for estimating the temperature rise. (Author abstract) 8 refs.

**079871 MEASURING METHOD ABOUT FLOW STRESS-STRAIN CHARACTERISTICS OF PLASTICS USING THE INDENTING HARDNESS TEST BY A SPHERICAL INDENTER.** This study deals with the measuring method about flow stress-strain characteristics of plastic using the indenting hardness test by a spherical indenter. First, hardness  $P_m$  (mean contact pressure)-total mean strain of an indentation  $\epsilon_{ic}$  characteristics are obtained with the indenting experiments by a spherical indenter, and flow stress  $Y$ -total strain  $\epsilon (= \epsilon_{ic})$  characteristics are measured using the uniaxial compression tests for plastic materials: PMMA, ABS, PC and PE. Second, Hardness/Flow stress ratio  $C$  is formulated,  $C = 9.8 P_m/Y$  in MPa, as the function of the ratio  $(\epsilon_{ic}/\epsilon_r)$ ,  $\epsilon_r$  is an elastic recovery strain  $(= E_0/E_s)$ ; Young's

modulus). Finally, it is shown that flow stress-strain characteristics from the elastic strain range to about the 10-15 percent strain range of plastics can be obtained using a one time indenting hardness test by a spherical indenter, by means of the calculation with the formulated equations in this paper and the former reports, and this method can be applied to the present hardness testing machines. (Author abstract). 14 Refs. In Japanese.

## Structural Application

**079872 ADVANCING STRUCTURAL PLASTICS INTO THE FUTURE.** A state-of-the-art background including the role of ASCE over the past 25 years is presented. During this time fiber-reinforced plastics (FRP) have been used effectively in civil engineering facilities such as pipes, water treatment plants, and structures exposed to highly corrosive environments. New or extended areas of research needed to provide civil engineers with the property data and structural behavioral information for structural plastics are discussed. Topics include infrastructure rehabilitation, characterization of composite materials, design guides for future materials systems, and adaptation of construction practice. Desired changes in governmental regulations and policies are offered and needed modifications to national educational programs are analyzed. (Edited author abstract) 13 refs.

**079873 EQUIPMENT FOR EXAMINING POLYMER MATERIALS IN CYCLIC LOADING.** Examination of the service loading of a number of plastic components of members of structures of gas transport equipment showed that they are subjected to the effect of various media and cyclic loading with various impact speeds, frequencies, and amplitudes. Therefore, in simulating their operating conditions, it is necessary to have a universal testing stand in which the loading parameters can be controlled in a wide range. The testing stand consists of equipment developing the multiple effect on the specimen in reciprocal movement of the slide block, control systems, control and measuring devices, and changeable additional devices which expand the test possibilities. Experience obtained using the proposed test unit, the loading regime, and the systems for measuring the loading parameters shows that the parameters can be regulated and controlled with sufficient accuracy. This indicates that the test unit is suitable for impact-fatigue and impact-abrasive tests of polymer materials.

**079874 HIGH SPEED COLOR PHOTOGRAPHY FOR STRAIN RATE MEASUREMENTS IN TENSILE TESTING OF PLASTICS.** Conventional high speed film photography is one of very few good methods

for strain measurement. Some reasons for this are discussed, with some comparison to the high speed video systems now on the market as the best known alternative. Cinematography had the advantage of making noncontact measurements over entire sample faces; it also provided, by definition, a permanent record of each test.

**079875 MEASURING METHOD ABOUT YOUNG'S MODULUS OF PLASTICS USING THE INDENTING HARDNESS TEST BY A SPHERICAL INDENTER.** This study aims at investigating the performance of a hardness testing machine. First, the phenomenon of a contact between a rigid spherical indenter and a plastic material is considered. By using Hertz's elastic contact law, the Young's modulus of plastics  $E_s$  can be calculated using the cordal diameter of an indentation  $d$ , the elastic recovery of an indentation. Furthermore, the mean strain rate under the elastic recovery by a spherical indenter is related to the strain rate under the uniaxial stress field. Finally, the indenting experiments are carried out. When the Young's moduli calculated from  $\delta t$  and  $\delta r$  using Eqs. (1)-(4) are compared to the Young's moduli measured from a compression test, their Young's values consist within an accuracy of about  $\pm 5-10\%$ . Therefore, the measuring method about Young's modulus of plastics using the indenting hardness test by a spherical indenter can be applied to the present hardness testing machines. **079876 INSTRUMENTED CHARPY IMPACT TEST OF POLYMERS.** The impact behavior of blunt and sharp-notched specimens of polypropylene (PP), polycarbonate (PC), polystyrene (PS), polyethylene (PE), poly(methyl methacrylate) (PMMA), propylene-ethylene block copolymer (PPB), and ABS plates has been studied using an instrumented Charpy impact tester. The load-time or -deflection curves of blunt-notched specimens have some oscillational load peaks before final fracture, which does not always occur at a maximum load value. The fracture origin for these specimens is located at the tip or within the plastic deformation zone which is formed at the notch root except for PS. The energy required for impact fracture corresponds well to the maximum elastic deflection energy of the specimen. (Edited author abstract) 12 refs. In Japanese.

## Thermal Conductivity

**079877 APPARATUS FOR MEASURING POLYMER THERMAL CONDUCTIVITIES AT HIGH PRESSURE AND TEMPERATURE.** Computer-aided design of plastic moldings requires knowledge of their thermal properties, e.g., thermal conductivity  $\lambda$ , under specific conditions. For this purpose, we constructed an apparatus that measures  $\lambda$  and functions within the 80-350°C temperature range up to a pressure of 500 bar. It was used to carry out experiments on three types of polymers (polyamide, polystyrene, and polypropylene). This paper includes a description of the experimental setup and a presentation of the numerical modeling required for simulating the thermal behavior of tested samples. (Edited author abstract) 15 refs.

**079878 GETTING THE BEST FROM TRANSFER MOLDING.** Of great importance to the process engineer is a basic understanding of the sensitivity of the molding process to variables, i.e., the parameters significantly affecting the total mold-filling history. The physical and esthetic properties of the molded part for a given mold design are directly related to molding conditions. The results of the experiments presented in this paper attempt to clarify this basic situation by monitoring the effect of the processing variable on the dynamic response of the transfer ram. All the experiments were carried out on a double-gated test-bar mold. 1 ref.

**079880 COME L'ARABA FENICE? [Like the Arabian Phoenix?].** A technology based on research of thirty years on polymeric microcrystals has been reposed for the disposal of plastics wastes. This should give back a second life to any used plastic. The article, that takes up a report by Raymond Seymour at the American Chemical Society's Symposium in Chicago, reviews the present state of wastes disposal techniques and the future prospects. (Author abstract) In Italian. 5 refs.

Anon. *Mater Plast Elastomeri* n 11 Nov 1986 p 571-575.

**079881 VALUE RECOVERY FROM PLASTICS WASTE BY PYROLYSIS IN MOLTEN SALTS.** A low temperature (420°-480°C) of pyrolysis minimizes the gaseous fraction, and allows liquid and solid fractions of high economic value to be obtained; these include light oils, aromatics, paraffin waxes and monomers. Molten salts, with their excellent heat transfer properties, are interesting media for rapid and regular pyrolysis (problem of reaction kinetics); a eutectic has been selected. Chlorine-containing plastics are also dechlorinated almost completely (using basic salts, which are consumed in the process). The results of laboratory tests on polyethylene, polypropylene, polystyrene and polyvinyl chloride are given. Considering the conclusions of the experiments and the possible economic applications, further developments relating to an industrial stage are discussed. (Author abstract) 7 refs.

## Wastes

**079882 GASIFICATION AND LIQUEFACTION FOR COVERING MATERIAL OF ELECTRIC CORD.** The covering material of an electric cord was pyrolyzed in an atmosphere up to 63wt percent and the others were produced as gases at the pyrolysis completion under the heating condition of 1°C/min. The partially combustion method and the high pressure pyrolysis method were conducted to reduce the solidified tar yield. The principal components of hydrocarbons in the partially combustion were  $C_1$ ,  $C_2$  and  $C_4$ . The hydrocarbons above  $C_5$  were not detected. The tar was reduced with increases of oxygen concentration and final temperature, while  $CO$  and  $CO_2$  increase with oxygen concentration. On the other hand, the solidified tar in the high pressure pyrolysis method was not produced on the range above 5kg/cm<sup>2</sup>, and the liquefied oil was done at 75wt percent of yield. (Author abstract). 6 Refs. In Japanese.

**079889 WELDING PLASTICS: A PRIMER.** As plastics have moved from non-critical applications, they have entered areas where structural and safety factors are of importance. Their joining is crucial to their more widespread industrial exploitation. This paper reviews various welding processes, emphasizing joint qualities obtainable, welding times, and suitability for different thermoplastic applications. (Edited author abstract)

Anon. *Automot Eng (Warrendale Pa)* v 94 n 12 Dec 1986 p 55-61.

**079890 HEATED-TOOL BUTT WELDING WITH CONSTANT WELDING SPEED.** Heated-tool butt welding is used in the manufacture of pipelines in the gas and water supply industries, as well as in series production for joining mouldings. High requirements are made for the quality of these joints. It is the aim of this paper to describe the effect of limiting the welding travel, which is frequently practiced during the welding of mouldings, and of a constant welding speed on the strength of the welded seam. The experimental investigations were performed with a fully automatic heated-tool butt welding machine. The test material was semi-finished material (extruded sheets) of HDPE. In English and German.

Potente, H.; Kreiter, J.; Mohrmann, A. *Kunstst Ger Plast* v 78 n 1 Jan 1988 p 29-30.

**079891 ULTRASONIC PLASTIC WELDING WITH WELDING TIP PAIR.** Ultrasonic plastic micro-welding with transverse and longitudinal vibration welding tip pairs is studied. (1) A welding tip pair of 20 kHz vibrating

perpendicularly, and (2) a welding tip pair of 20 kHz and 27 kHz vibrating parallel to the surfaces to be welded are used for micro-welding of plastic sheet specimens. The welding tips are arranged parallel to each other with a small gap and driven at antiphase vibration mode. Using these welding tip pairs, welding specimens are joined with very narrow width from the upper part of lapped specimens according to the gap distance with no damage to the lower part of the specimens. **079893 INVESTIGATION OF OPEN CIRCUIT REACTIONS OF POLYMER FILMS USING THE QUARTZ CRYSTAL MICROBALANCE. REACTIONS OF POLYVINYLFERROCENE FILMS.** Bimolecular reactions between polyvinylferrocene (PV-Fc) films at open circuit and solution species that are accompanied by mass changes in the polymer have been investigated with a quartz crystal microbalance (QCM). PV-Fc oxidation by  $I_2/I_3^-$  and PV-Fc<sup>+</sup> reduction by Fe<sup>II</sup>(CN)<sub>6</sub><sup>4-</sup> and Ru(NH<sub>3</sub>)<sub>6</sub><sup>2+</sup> can be monitored with the QCM by following the formation of PV-FcI<sub>3</sub> in the former reaction and the expulsion of counteranions from the polymer film in the latter two processes. Rate constants can be estimated and reaction mechanisms postulated based on the temporal response of the frequency shift that occurs upon switching the films to open circuit from a potential which electrochemically maintains the active redox state of the polymer. (Edited author abstract) 35 refs.

Ward, Michael D. (DuPont, Wilmington, DE, USA). *J Phys Chem* v 92 n 7 Apr 1988 p 2049-2054.

**079894 ELECTROACTIVITY OF TRANSPARENT COMPOSITE FILMS FROM CONDUCTING POLY(THIOPHENES).** Conducting composite films containing an electropolymerizable conducting polymer such as poly(3-methylthiophene) (PMeT) alloyed with poly(vinyl chloride) (PVC) have been prepared in a one-step process from synthesis media already containing dissolved PVC. This procedure based on the simultaneous electropolymerization and dip-coating processes allows a large control of the composition, morphology, optical transmittance, conductivity, and electroactivity of the composite films. The growth of PMeT in synthesis media containing dissolved PVC has been analyzed. Increasing the PVC concentration produces a slight decrease of the MeT electropolymerization rate with no apparent modification of the polymerization mechanism. The electrochemical properties of the composite films have been investigated in acetonitrile by using cyclic voltammetry and chronoamperometry. (Edited author abstract) 22 refs.

**079898 FURTHER CONSIDERATIONS OF THE MECHANISM OF GAS DIFFUSION IN GLASSY POLYMER FILMS.** In glassy polymers, the penetrant molecules are retained in two distinct ways, namely via Henry's Law dissolution in the polymer matrix and Langmuir-type adsorption in unrelaxed microvoids (dual-mode sorption model). In terms of R.M. Barrer's suggestion that the two kinds of retained penetrants should undergo diffusive movements within the two respective modes and execute jumps between the two modes the mean permeability coefficients driven by gradients of concentration and chemical potential are

derived. From a comparison of permeability data with one of the author's equations, plausible values of diffusivities  $D_{DD}$ ,  $D_{DH}$ , and  $(D_{HD} + D_{HH})$  can be determined, but the values of both  $D_{HD}$  and  $D_{HH}$  cannot be evaluated separately. By use of Onsager's reciprocity relation, however, the value of  $D_{HD}$  can be calculated with an estimated value of  $D_{DH}$ . Consequently, the value of  $D_{HH}$  can be also calculated, and the values of all of four kinds of diffusivities can be determined. 6 Refs.

**079901 COUNTERCURRENT COOLING OF BLOWN FILM.** Presently used methods for the external cooling of blown film involve the use of an air ring located at the base of the bubble that blows air upward along the surface of the bubble. The air is heated as it rises, while the film is cooling and moving in the same direction. This is an example of occurrent heat exchange, and the result is the accumulation of heated air around the upper portion of the bubble, which interferes with the cooling in this region. While rapid initial cooling is required to maintain bubble stability, we have explored the possibility of using countercurrent cooling for the upper region of the bubble. A standard air ring is mounted at the base of the bubble, and a circular shroud surrounds the bubble above this air ring. All the heated air is collected in an upper chamber surrounding the shroud and is exhausted by means of a secondary blower. (Edited author abstract) 11 refs.

**079902 DRAW RESONANCE IN FILM CASTING OF VISCOELASTIC FLUIDS: A LINEAR STABILITY ANALYSIS.** In order to understand the role of viscoelasticity on draw resonance in the isothermal film casting process, a steady state analysis and a linear stability analysis for three-dimensional flow disturbances have been conducted. The constitutive equation used is a modified convected Maxwell model, with shear-rate dependent viscosity and fluid characteristic time. The numerical results indicate that the flow is stable below a lower critical draw ratio and above an upper critical draw ratio. Shear thinning in viscosity reduces the lower critical draw ratio and somewhat increases the upper critical draw ratio - thereby enlarging the region of instability. Slower shear reduction in fluid characteristic time dramatically decreases the upper critical draw ratio but has no significant effect on the lower critical draw ratio; therefore, fluids with higher characteristic time are more stable. (Author abstract) 17 Refs.

**079903 COEX COMMODITY FILMS ARE ALIVE AND GROWING.** Coextruded grocery sacks and merchandise bags combine gloss and print appeal of LLDPE with downgaged toughness of straight HMW products. High-volume IBC stabilized line at Hilex Poly is claimed to make them at rates competitive with monolayer blown film equipment. HMW/LLDPE coextrusions have retained their competitive edge because they offer unique ways to meet customer requirements without increasing product costs. Ultra-Tech Plastics, Mansfield, OH, was among the first to start up a coex line for commodity films, and has no intention of rethinking its decision. Unlike HMW monolayer, HMW/LLDPE films can be heat-sealed on conventional multilane bagmaking machines. Thus, bigger and wider-layflat coex lines are a prime thrust of equipment development. Another new coex productivity concept is application of barrier screw technology to grooved feed HMW layer extrusion. Sano Design's triple-source IBC bubble cooling system is said to double line throughput and is recommended by the company as a key element in bigger coex lines.

**079904 THIN POLYMER FILMS FROM FLUIDIZED ELECTRODE BED REACTORS.** The formation and deposition of a polymer as a thin, uniform solid film on a metal particle substrate is investigated in detail in a fluidized electrode bed reactor. Experiments were carried out in different designs of fluidized bed electrode cell reactor, using various metal particles and monomers. It was observed that diacetone acrylamide (DAA) monomer in 0.1N  $\text{H}_2\text{SO}_4$  with aluminum particles (3530  $\mu\text{m}$ ) as cathode, in a concentric dual compartment cell, appeared to yield the best films. Infrared and elemental analyses were used to characterize the polymer film on the metal particles. Scanning electron microscopy (SEM) was employed to examine the surface and cross-sectional profiles of the films. (Edited author abstract) 19 refs.

## Corona

**079906 INTERNAL POLARIZATION IN POLYTETRAFLUOROETHYLENE FILMS SUBJECTED TO THE EFFECT OF A CORONA DISCHARGE.** The presence of internal polarization (heterocharge) in nonpolar polytetrafluoroethylene films electrified in a corona discharge was found experimentally. This resulted from an analysis of graphs of the electret potential as a function of the charge imparted to the films and current of thermally stimulated depolarization in experiments with a dielectric gap and change in the potential during heating. The extremely high stability of the electret potential in charged PTFE films is explained by slow relaxation of the heterocharge. (Edited author abstract) 8 refs.

**079907 FORMATION OF AN ELECTRIC DOUBLE LAYER DURING THE DISSOLUTION OF A PHENOL-FORMALDEHYDE RESIN FILM.** A simplified mathematical model of the dissolution of a phenol-formaldehyde resin film in a solution of NaOH has been devised. In a first approximation to the solution of the problem it was assumed that the replacement of the hydrogen atom of one hydroxyl group by sodium is sufficient for the passage of a resin molecule into the solution. The model adopted provides a qualitatively current description of the experimentally obtained dependence of the rate of dissolution on the concentration of NaOH and on the concentration of an addition of a neutral salt. This work is pertinent to photoresists. (Edited author abstract) 5 refs.

**079908 MEASURING AND MODELLING THE TRANSITION LAYER DURING THE DISSOLUTION OF GLASSY POLYMER FILMS.** The technique of laser interferometry is now used routinely by the microelectronics industry for the measurement of the dissolution rates of thin polymer films. In addition to the rate of dissolution laser interferometry can also provide

quantitative information on the thickness of the transition layer between the dissolving glassy polymer and the liquid solvent. This paper describes how observed patterns of reflected light intensity may be analyzed to calculate the thickness of the transition layer for polymers that dissolve with little or no swelling. The technique requires knowledge of the shape of the concentration profile in the transition layer. However, by assuming various simple model profiles one may obtain a reasonable estimate. Experimental measurements of poly(methyl methacrylate) (PMMA) films dissolving in methylethyl ketone indicate transition layers of thicknesses 0 to 0.1  $\mu\text{m}$  for PMMA of molecular weights  $M_w = 37,000$  to 1,400,000. **079909 POLYPYRROLE AND POLY(N-METHYLPYRROLE) FILMS DOPED WITH KEGGIN-TYPE HETEROPOLYANIONS: PREPARATION AND PROPERTIES.** Solutions of pyrrole in acetonitrile in the presence of Keggin-type heteropolyacids (HPA) such as  $(\text{SiW}_{12}\text{O}_{40})^{4-}$  and  $(\text{PW}_{12}\text{O}_{40})^{3-}$  yield soluble complexes. Oxidation of the complexes gives polypyrrole films doped by the HPA. The electrochemical behavior of the HPA immobilized in several film thicknesses is described. It is different for HPA alone in solution because of the lack of conductivity of the polypyrrole and poly(N-methylpyrrole) in the potential range of reduction and in the range of molecular dispersion of HPA in the polymer matrix. The levels of doping of the polymers by HPA are similar to those with classical anions, but here the HPA are retained in the films rather better even upon cycling. (Author abstract) 31 Refs.

**079910 ON THE RHEOLOGY OF COLD DRAWING. I. ELASTIC MATERIALS.** In this, the first paper in a series on neck formation and steady-state drawing of polymeric fibers and films under uniaxial tension, the emphasis is laid on those aspects of the mechanics of cold drawing that are not sensitive to viscoelastic effects and, therefore, can be treated by use of constitutive assumptions appropriate to elastic materials. It is here shown that a unidimensional theory which has been employed to model the mechanics of slender bars in tension can be derived as an approximation for three-dimensional bars and, in a sense which can be made precise, is valid to within an error of the order of the fourth power of the thickness. A particular constitutive equation for incompressible, three-dimensional, elastic materials is explored in detail and is found to yield, for such slender bars as thin fibers and wide (but thin) strips of film. (Edited author abstract) 12 Refs.

## Electric Breakdown

**079912 BREAKDOWN OF POLYETHYLENE FILM-LIQUID NITROGEN COMPOSITE SYSTEMS.** The breakdown characteristics reported depend on the number of film layers in the sample, the electric field distribution inside the film, and the front time and polarity of the applied impulse voltage. Three effects are discussed: (1) the effect of field distribution by which a strong field at the film surface triggers a breakdown streamer and the streamer development is supported by the field inside the film; (2) the effect of front time by which the breakdown voltage is considered to be governed by the breakdown time lag and the injected charge density which increases with the front time of the applied impulse voltage; and (3) the effect of number of layers, i.e., the sample with the larger number of layers has a higher resistance to impulse voltage. 17 refs.

**079913 PREPARATION AND ELECTROCATALYTIC PROPERTIES OF CONDUCTING FILMS OF POLYPYRROLE CONTAINING PLATINUM MICROPARTICULATES.** Metallic particles were dispersed in electrically conducting polymer films in order to achieve multi-electron transfer processes in a three-dimensional matrix. Dispersions of Pt in polypyrrole were formed by several electrochemical and chemical methods, and the concentration profiles were determined by Auger Electron Spectroscopy (AES). Films were prepared in which Pt was deposited primarily at the polymer/solution interface, at the metal/polymer interface, or uniformly through the film. The electrocatalytic reduction of oxygen was investigated by rotating disk electrode studies with these films. For the homogeneous film, the catalytic current is limited by the rate of  $\text{O}_2$  permeation in the film. (Author abstract) 22 refs.

Holdcroft, Steven (Simon Fraser Univ, Burnaby, BC, Can); Funt, B. Lionel. *J Electroanal Chem Interfacial Electrochem* v 240 n 1-2 Jan 25 1988 p 89-103.

**079914 ELECTRICAL CONDUCTIVITIES OF FILMS OF POLYMER COMPLEXES BETWEEN ELECTRON-DONATING POLYMERS AND ALUMINIUM COPPER(I) CHLORIDE.** Homogeneous films of polymer complexes between aluminium copper(I) chloride and poly(p-methylstyrene), poly(p-bromostyrene), poly(p-chlorostyrene), poly(p-methoxystyrene), or poly(m-methylstyrene) were prepared. A linear relationship was observed between logarithm of direct current conductivity of the film and the corresponding Hammett substituent constants for the films of poly(p-methylstyrene), poly(p-bromostyrene), poly(p-chlorostyrene), poly(m-methylstyrene), and unsubstituted polystyrene. It has been shown that the electrical conductivities of the films of the polymer complexes are associated with the charge-transfer interactions between the electron-donating polymer and aluminium copper(I) chloride. (Edited author abstract) 4 refs. In Japanese.

**079915 IN SITU CONDUCTIVITY AND PHOTOCONDUCTIVITY MEASUREMENTS OF POLYANILINE FILMS.** In situ conductivity measurements on a polyaniline film with a fourprobe electrode are performed in  $\text{NH}_4\text{F}$ , 2.3HF and in propylene carbonate in the dark and under illumination. The conductivity is also determined on a pellet of chemically prepared polyaniline mixed with carbon black as for a battery electrode. The upper values of conductivities are  $120 \text{ ohm}^{-1} \text{ cm}^{-1}$  in the hydrofluoric medium,  $25 \text{ ohm}^{-1} \text{ cm}^{-1}$  in propylene

carbonate and  $8 \text{ ohm}^{-1} \text{ cm}^{-1}$ . The increase in conductivity of the polyaniline film in the solid state upon illumination is about  $0.7 \text{ ohm}^{-1} \text{ cm}^{-1}$  (10 percent). (Author abstract). 21 Refs.

Genies, E.M. (CEN, Grenoble, Fr); Hany, P.; Lapkowski, M.; Santier, C.H.; Olmedo, L. *Synth Met* v 25 n 1 Jul 1988 p 29-37.

**079916 STRUCTURE, STRENGTH AND ELECTRICAL PERFORMANCE OF CONDUCTING POLYPYRROLES.** Polypyrrole films, typically 0.2 mm thick, were prepared by electrodeposition with p-toluene sulphate as dopant anions. Conductivities of up to  $340 \text{ S cm}^{-1}$  were found, comparing favourably with other cited examples. Conductivity along each sample was found to be much greater than across: such asymmetry may be exploitable. Electrodeposition temperatures ( $0^\circ\text{C}$ ) lead to higher conductivities than at  $25^\circ\text{C}$ . The structure was amorphous as indicated by X-ray diffraction, and the morphology was found to be nodular by using optical and scanning electron microscopy. Films were found to be quite strong and tough, although some reduction in mechanical performance was found after ageing in air. Fracture surfaces of tensile test pieces suggest a layered structure, with little evidence for viscous deformation being evident. (Author abstract). 21 Refs.

Cvetko, B.F. (Univ of New South Wales, Kensington, Aust); Brungs, M.P.; Burford, R.P.; Skyllas-Kazsacos, M. *J Mater Sci* v 23 n 6 Jun 1988 p 2102-2106.

**079917 POLYANILINE FILMS. ELECTROCHEMICAL REDOX MECHANISMS.** The different redox mechanisms proposed in the literature concerning the electron and proton transfers that occur in polyaniline (PANI) films are presented and discussed. The electrochemical behavior of PANI usually shows two pairs of current peaks on cyclic voltammeter curves in aqueous or organic medium. In situ spectroelectrochemical and EPR studies of PANI synthesized in  $\text{NH}_4\text{F}$ , 5.3HF were carried out in association with cyclic voltammetry. The results are discussed in terms of the redox reaction mechanisms. The authors propose that the complete redox mechanism involves four one-electron steps and two polaron-bipolaron states in PANI films. (Author abstract) 34 refs.

Genies, E.M. (Cent d'Etudes Nucleaire, Grenoble, Fr); Lapkowski, M. *Synth Met* v 24 n 1-2 Apr 1988, Proc of the Second Fr-Pol Colloq on Low Dimens Org Conduct and Electroactive Polym, Nancy, Fr, May 12-15 1987 p 61-68.

**079918 SPECIFIC KINETIC FEATURES OF THE REVERSIBLE REDOX REACTION OF CONDUCTING POLYPYRROLE FILMS IN AQUEOUS MEDIA.** In this work cyclic voltammetry and a radiotracer technique are used to investigate the kinetics of the reversible redox reaction of PP films in aqueous media. The PP films were obtained galvanostatically by anodic polarization of Pt electrodes in a divided cell using aqueous 0.1 M pyrrole solutions with 0.1 N  $\text{H}_2\text{SO}_4$  or  $\text{HClO}_4$  as the base electrolyte. It was found as a result of the work that the rate of PP oxidation and reduction is limited chiefly by anion diffusion in the film, that the diffusion rate depends on acidity of the electrolyte solution, and that the cycle of oxidation and reduction can be continued for several hours over practically the full depth of the PP films up to a thickness of  $40 \mu\text{m}$ , which is rather more than the thickness of the films studied in aprotic media. 4 refs.

Kras'ko, V.V. (L. Ya. Karpov Physicochemical Scientific-Research Inst, Moscow, USSR); Yakovleva, A.A.; Kolotyrlin, Ya.M. *Sov Electrochem* v 22 n 9 Sep 1986 p 1137-1140.

**079919 ANISOTROPIC ELECTRICAL AND OPTICAL PROPERTIES OF ELONGATED POLY(P-PHENYLENE VINYLENE) FILM.** Anisotropic photoconductivity of an oriented form of poly(p-pheny-

lene vinylene) has been studied. The photocurrent spectrum for the light polarized parallel to the chain direction is much enhanced in lower photon energy as compared with that for the light polarized perpendicular to that direction. The result may be originated in the difference of energies which is needed to photogenerate carriers with the light polarized parallel and perpendicular to the chain direction, respectively. There is anisotropy of the conductivity in the stretched PPV film heat-treated at  $1000^\circ\text{C}$ . This anisotropy can be explained by the difference of carrier mobilities parallel and perpendicular to the stretched direction. (Author abstract) 5 refs.

Tagiguchi, Tohru (Osaka Univ, Jpn); Park, Dae Hee; Sugimoto, Ryu-ichi; Ueno, Hideki; Yoshino, Katsumi. *Technol Rep Osaka Univ* v 37 n 1865-1888 Mar 1987 p 111-116.

**079920 ELECTRICAL PROPERTIES OF POLY(2,5-DIBUTOXY PHENYLENE) FILM.** Solid state properties, especially properties, of poly(2,5-dibutoxy phenylene) (PDBP), one of the derivatives of poly(p-phenylene) (PPP), have been studied. Tough and flexible PDBP films obtained by casting from a toluene solution were used. From the studies of dielectric relaxation and dynamic viscoelasticity, two types of molecular motion, twist motion of main chains and local motions of butoxy groups, were found. The processibility of PDBP was attributed to the presence of these molecular motions. It was concluded that the introduction of a butoxy group into phenylene rings has little effect on the electronic structure of PPP. (Edited author abstract) 15 refs. In Japanese.

Yamada, Shingetsu (Kyushu Univ, Fukuoka, Jpn); Tokito, Shizuo; Tsutsui, Tetsuo; Saito, Shogo. *Kobunshi Ronbunshu* v 44 n 5 1987 p 399-403.

**079921 ELECTRICAL CONDUCTION OF  $\text{Cu}_x\text{S}$ -TREATED FILMS.** Electrical conductivity measurements have been made on  $\text{Cu}_x\text{S}$ -treated PET and nylon 6 films in the temperature region between 20 and  $200^\circ\text{C}$ .  $\text{Cu}_x\text{S}$ -treated films have been observed to have two transition temperatures at about 100 and  $180^\circ\text{C}$ , respectively. It should be reasonable to consider that the conductivity behavior between 100 and  $180^\circ\text{C}$  is attributed to the character of a metastable structure of the cuprous sulfide. Temperature dependence of conductivity of the  $\text{Cu}_x\text{S}$ -treated PET and nylon 6 films was investigated and compared with that of original PET and nylon 6 films. The current-voltage characteristics and time dependence of conductivity of samples were investigated. Conduction mechanism of the  $\text{Cu}_x\text{S}$ -treated films was not dependent on matrix polymers but dependent on  $\text{Cu}_x\text{S}$  crystal, and the conduction is mainly electronic. (Author abstract) 12 refs.

Im, Sung Soon (Hanyang Univ, Seoul, South Korea); Kang, Eun Young. *J Appl Polym Sci* v 35 n 2 Feb 5 1988 p 475-483.

**079922 ELECTRIC PROPERTIES OF INERT POLYMER FILMS DOPED WITH ELECTROLYTES.** Polyvinyl chloride films, doped with Aliquat chloride or Aliquat ferro/ferricyanide, were studied by the ac impedance and dc polarization methods. Effects of composition variation and temperature on conductivities and capacitances were measured. It is probable for M/F/M cells, where M=metal and F=membrane film, that interfacial charge transfer is electrochemical (e.g., redox) at the interfaces for high applied voltages, regardless of the single Aliquat salt used, and charge conduction in the bulk is ionic. There is no evidence for electronic conductivity even for mixtures of ferricyanide/ferricyanide. Redox reactions of trace oxygen, water or other impurities are involved at the interfaces when there is no principal reaction possible, such as oxidation of metal or ferrocyanide, or reduction of ferricyanide. (Edited author abstract) 21 refs.

**079923 CHANGE OF ELECTRICAL PROPERTIES OF PLASMA-POLYMERIZED FILMS FORMED FROM HEXAMETHYLDISILOXANE WITH TREATMENT BY ELECTRICAL DISCHARGES.** By means of a parallel-plate electrodes system, plasma-polymerized films (PPHF) formed from hexamethyl-disiloxane were treated by electric discharges in the air. The samples were examined with regard to changes in infrared absorption spectra, ESCA spectra, contact angle, surface resistivity, capacitance, and loss tangent. The results of infrared absorption spectra and ESCA spectra of treated PPHF showed that hydroxyl and carbonyl groups and nitrogen compounds were introduced, and that the atomic ratio of carbon to silicon decreased, while that of nitrogen and oxygen increased with treatment time. The contact angle of the untreated PPHF for water was  $103^\circ$ ; however, the water drop spread out after treatment. (Edited author abstract) 14 refs. In Japanese.

**079924 FREE-STANDING, CONDUCTING FILMS OF PYRROLE/ N-(4-FERROCENYLBUTYL)-PYRROLE BENZENESULPHONATE COPOLYMERS.** The electrochemical preparation, in a flow-through cell, of self-supporting films of a pyrrole/N-( $\omega$ -ferrocenylbutyl)-pyrrole copolymer with benzenesulphonate as a dopant anion is described. For comparison, polypyrrole benzenesulphonate was made under the same conditions. The polymer films were characterized by complete elemental analysis, i.r. spectroscopy, conductivity at various film potentials, scanning electron microscopy and dynamic elastic modulus measurements and their temperature dependence. Copolymerization is shown to be a viable method for producing redox-modified polypyrrole films when moderate conductivity and limited mechanical strength are acceptable. (Author abstract). 34 Refs.

Merz, A. (Univ Regensburg, Regensburg, West Ger); Haimel, A.; Owen, A.J. *Synth Met* v 25 n 1 Jul 1988 p 89-102.

**079925 ELECTROCHEMISTRY OF POLYPYRROLE FILMS.** Electrochemically prepared films of polypyrrole have been studied as electrode coatings in an electrochemical cell with potassium ferricyanide as the electroactive species in solution. The electrode-solution interface was studied by ac impedance measurements over the frequency range  $0.003\text{--}10^5 \text{ Hz}$ . A novel model circuit description of the electrode-electrolyte interface was devised, which consisted of seven elements (including a frequency-dependent Warburg impedance) for the bare platinum electrode and ten elements (including an additional Warburg impedance concerned with film oxidation and reduction) for the polypyrrole-coated electrodes. The values of the circuit elements were calculated by computer fitting and excellent agreement was found between measured impedances and those predicted from the calculated circuit element values. **079926 ELECTROCHEMISTRY OF POLYTHIOPHENE AND POLYBITHIOPHENE FILMS IN AMBIENT TEMPERATURE MOLTEN SALTS.** Polythiophene and polybithiophene polymer films were deposited on platinum, tungsten, and glassy carbon electrodes by anodic oxidation of the monomer in ambient temperature molten salts, consisting of a mixture of aluminum chloride and 1-methyl-3-ethyl-imidazolium chloride. The formation reaction of polythiophene and polybithiophene is totally irreversible. The polymer films are conductive in the oxidized state and nonconductive when reduced as indicated by the shape of cyclic voltammetric curves for the polymers and for ferrocene oxidation on electrodes

covered by different thicknesses of polymer. Results of ferrocene oxidation on electrodes coated by polythiophene suggest that these polymer films are porous. (Edited author abstract) 46 refs.

Janiszewska, Laura (State Univ of New York at Buffalo, Buffalo, NY, USA); Osteryoung, Robert A. *J Electrochem Soc* v 134 n 11 Nov 1987 p 2787-2793.

**079927 INFLUENCE OF LIGHT ON THE ELECTROCHEMICAL BEHAVIOUR OF POLYANILINE FILMS.** The electrochemical behavior of polyaniline (PANI) films under irradiation was studied in  $\text{NH}_4\text{F}$ , 2.3 HF solution and in acetonitrile, 0.5 M  $\text{LiClO}_4$ . It is found that the polymer displays a very fast photoresponse to a near-infrared light pulse (50  $\mu\text{s}$ ), which we associated with rapid modifications in its electric properties. On a longer time scale, photoelectrochemical effects were observed, with injection of electrons or holes in the solution. With chloral in  $\text{NH}_3/\text{HF}$  solution, an efficient photoreduction of the aldehyde was obtained. PANI can thus be considered as a p-type semiconductor useful for photoelectrochemical conversion of light to electricity or for photoassisted electrosynthesis. (Author abstract) 18 refs.

**079928 NOW DOWNSTREAM CALLS THE SHOTS IN BLOWN FILM PRODUCTIVITY.** Improvements in melt conditioning brought about by the first generation of blown film lines, and lifting of bubble cooling-related rate limitations by the second generation, have set the stage for better ways to handle and wind the now-faster-moving film bubble in order to reach productivity and quality goals that until very recently were considered unattainable. For virtually every type of resin, from forging low and medium density polyethylenes to progressively harder-to-handle high molecular weight PE and engineering resins like polycarbonates and nylons, there are innovative new ways to handle the melt after it leaves the extruder. What these new methods hold in the cards for the processor are blown film lines that can handle more than 2000 lb. of resin per hour at throughput rates of 700 ft./min and more - with film quality superior to that currently found on the most advanced cast film line.

Sneller, Joseph A. *Mod Plast* v 65 n 1 Jan 1988 p 52-54, 56, 58.

**079929 EXTRUSION TARGET: HIGHER QUALITY, MATERIAL SAVINGS.** Tightening the screws on product quality and 'stretching' materials utilization are the twin foci of much of the newest extrusion technology. Concrete steps being taken to achieve those goals in film, sheet, pipe and profile extrusion is the subject of this report. All major extrusion systems suppliers have been consulted for this. Much of what they revealed involves departures from prior convention. This report is necessarily selective, concentrating on those areas of extrusion identified by machinery suppliers and extrusion processors as the ones where the most new technology is being developed. Not surprisingly, those are also typically areas believed to show greatest potential market growth.

Kreisher, Keith (Plastics Technology, New York, NY, USA). *Plast Technol* v 34 n 2 Feb 1988 p 46-53.

**079930 WITH EFFICIENT DIE AND TOWER DESIGN YOU CAN CUT DOWNTIME IN FIVE-LAYER FILM EXTRUSION.** A new five-layer blown film line that was recently installed at the Applications Research Laboratories of the USI Div. of Quantum Chemical Corp. That line (one of six) has several features designed to minimize downtime for cleaning, facilitate startup, minimize floorspace requirement, and also to ensure production of high-quality film rolls. Because a

large number of multilayer blown film lines are being installed nowadays, many of them for five-layer packaging, it is hoped that a discussion of this production-scale lab line could provide a useful example for processors. This line is available for customer demonstrations, trial runs, and training.

Prall, George M. *Plast Technol* v 34 n 2 Feb 1988 p 55-57.

**079931 ORIENTATION, CRYSTALLIZATION, AND HAZE DEVELOPMENT IN TUBULAR FILM EXTRUSION.** A critical review of research on the development of crystallinity, orientation, and haze in tubular film is presented. We examine the basic methods of characterization of polymer films and interpretation of experimental techniques. Most studies in the literature relate to polyethylene, polystyrene, and polypropylene tubular film. Polymer chain and crystallographic axis orientation have been studied using x-ray diffraction and birefringence. We critically discuss the representation of such data using biaxial orientation factors. The data appear correlatable in terms of expressing orientation as a function of applied stresses at solidification. It appears that a film haze is predominantly caused by surface roughness. This is largely associated with the crystallization of the melt on the process line. (Author abstract) 145 refs.

**079932 DISTRIBUTIA TEMPERATURII LA CURGEREA IN FILME SUBTIRI A LICHIDELOR NENEWTONIENIE CE RESPECTA MODELUL OSTWALD DE - WAELE IN CONDITILE UNUI FLUX TERMIC CONSTANT LA PERETE SI ALE UNEI VISCOZITATI MARI.** [Temperature Distribution in Thin Film Flow of Nonnewtonian Liquids Observing the Ostwald de Waele Model Under Constant Wall Heat and High Viscosity Conditions]. The dimensionless temperature distribution is determined for the thin film flow of pseudo-plastic liquids, under conditions of constant wall heat flux and high viscosity of the nonnewtonian fluid. The analysis of the theoretical temperature distribution in the film shows that the effect of the viscous dissipation may be ignored. The experimental data are satisfactorily approximated by the theoretical equations. (Author abstract). 15 Refs. In Romanian.

**079933 NUCLEAR MAGNETIC RESONANCE STUDY OF FILM FORMATION DURING HYDROLYTIC POLYCONDENSATION OF TETRAETHOXY-SILANE IN AN ACID AQUEOUS-ALCOHOLIC MEDIUM.** The objective of this investigation is to study the course of molecular processes during film formation in an aqueous-alcoholic medium in presence of an acid catalyst and a polymer dispersion. Preliminary investigations of the three-component system ethyl alcohol-water-TES showed that in a freshly prepared solution the PMR signals of ethoxy groups of the alcohol and TES are observed separately. Experimental data indicate that a polymer film is formed during the first stage, but it still contains a rather large amount of solvent. At the second stage evaporation and polycondensation processes slow down considerably because of the high viscosity of the films. After 30 h of drying at room temperature a fairly large amount of hydrogen-containing atomic groups remains in the films. 7 refs.

**079934 RADIATION-POLYMERIZATION OF HEPTYLMETHACRYLATE IN PRESENCE OF BUTADIENE-NITRILE RUBBER.** With increase in the initial concentration of SKN-18 in its composite with heptylmethacrylate auto-acceleration of the polymerization process shifts to the region of shorter  $\gamma$ -radiation times and for a content of 60 wt percent of the rubber polymerization of the monomer proceeds instantly in conditions close to those of the gel effect. The mixed character of termination of the polymer chains is observed and at the final stage of post-polymerization at 295 K linear termination predominates. The rate constant of growth of the polymer chains in the interval 170-180 K has been determined:  $k_p = 2 \times 10^{-13} \exp(-6000/RT)$   $\text{cm}^3\text{sec}$ . Introduction of small additions of the monomethacrylic ester of ethylene glycol (crosslinking agent) raises the rate of the process. (Author abstract).

**079935 XP-SPECTRA, SPUTTEREXPERIMENTS AND UV-VIS-REFLECTION SPECTRA OF POLYANILINE.** Electrochemical formed polyaniline (PANI) films were studied both in situ and ex situ using XPS and UV/VIS spectroscopy. The samples studied ex situ were removed at given potentials and rinsed with water, with no changes in the oxidation state or concentration of counter ions. PANI-RED (0.0 V (SHE)) contained no anions and the XP-spectra showed an emeraldine-like structure and 0.27 protonated nitrogen atoms/monomer. PANI-OX (1.0 V (SHE)) contained 0.2 - 0.3 counter ions/monomer throughout the film. UV/VIS spectroscopy shows a two step redox mechanism involving radical cations. The extended conjugation of PANI-OX was followed by both reflection spectroscopy and XP-shake-up peaks accompanying the photoionisation process. At potentials above 1.0 V (SHE) overoxidation occurs with the removal of anions from the bulk film. (Author abstract). 16 Refs.

**079936 POST-RADIATION GRAFTING OF STYRENE TO POLYETHYLENE FILM AND DISTRIBUTION OF GRAFTED POLYSTYRENE.** Post-radiation grafting of styrene to PE film irradiated in air by  $^{60}\text{Co}$  source of  $\gamma$ -radiation and by an electron accelerator was studied. The effect of ferrous salt additives on the kinetics of this process is demonstrated. The distribution of grafted PS in PE was analyzed by IR absorption and ATR spectra in dependence on the intensity and dose of radiation. Diffusion of ferrous ions into the film was found to play a determining role in the kinetics of grafting polymerization and in distribution of PS in the film. (Author abstract) 13 refs.

**Ion Implantation**

**079937 EFFECTS OF ION IMPLANTATION ON POLY(DIMETHYLSILYLENE-CO-METHYLPHENYLSILYLENE).** The effects of ion implantation on the electrical and structural properties of poly(dimethylsilyl-

lene-co-methylphenylsilylene) (DMMPS) thin films have been investigated. Ionic species of krypton, arsenic, fluorine, chlorine, and sulfur were implanted at energies ranging from 35 to 200 keV and with doses of up to  $1 \times 10^{16}$  ion/cm<sup>2</sup>. The conductivity of the polymer increased upon implantation reaching a maximum value of  $9.6 \times 10^{-6}$  ( $\Omega$  cm)<sup>-1</sup> for the case of arsenic ion at a dose of  $1 \times 10^{16}$  ion/cm<sup>2</sup> and energy of 100 keV. The results showed that ion implantation induced conduction in DMMPS was primarily due to structural modifications of the material brought about by the energetic ions. Infrared analysis and Auger electron spectroscopy showed evidence for the formation of a silicon carbide-like structure upon implantation. (Author abstract) 13 refs.

**079938 CONDUCTIVITY BEHAVIOUR OF GAMMA-IRRADIATED PEO-LIX ELECTROLYTES. I.** In an attempt to enhance the room temperature ionic conductivity of PEO-LiX films, samples have been exposed to gamma-irradiation at 78°C. The success with which cross-links have been introduced into the amorphous form has been evaluated from d.s.c. analysis and temperature-dependent conductivity data. Retardation of the recrystallization event, associated with uncomplexed poly(ethylene oxide), does not occur over a range of total doses. Changes in overall conductivity levels for the PEO-LiCF<sub>3</sub>SO<sub>3</sub> system indicate light cross-linking at 2.25 Mrad of exposure. (Edited author abstract) 8 refs.

## Latex

**079940 FTIR-ATR SPECTROSCOPIC DETERMINATION OF THE DISTRIBUTION OF SURFACTANTS IN LATEX FILMS.** FTIR-ATR (Fourier Transform Infra-Red-Attenuated Total Reflection) has been used to analyze the surface composition of coalesced acrylic latex films. The behavior of two anionic surfactants has been characterized. It has been found that surfactant distribution depends on the nature of the surfactant. A comparison between the normalized absorbance in transmission and in reflection has shown an enrichment of surfactants at the surfaces of films with a coalescence time of 3 days. The surfactant concentration at the film-air interface is higher than at the film substrate interface. A concentration gradient exists through the film thickness. In addition, the incompatible surfactant migrates towards the interface as coalescence proceeds. (Author abstract) 26 refs.

## Mathematical Models

**079942 INTERACTION OF CRYSTALLINITY, ELASTOPLASTICITY, AND A TWO-PHASE MODEL ON BLOWN FILM BUBBLE SHAPE.** Historically, simulations of the blown film process have been carried out only to the freeze line; a point which is often well below the actual frost line for the process. This limitation in previous simulations was discovered to be related to the interaction of the process boundary conditions with the rheological equation of state used in previous analyses to represent the stretching of the polymer film. A new approach has been developed that allows the process to be simulated to the real frost line. This has been accomplished by using a two-phase model incorporating viscoplasticity and crystallization of the polymer melt into the physical description of the blown film process. Prediction of the bubble shape, temperature, and velocity from the die to the frost line agree fairly well with experimental data. (Edited author abstract) 19 refs.

**079947 FLEXIBLE POLYANILINE.** Flexible polyaniline having excellent mechanical properties was prepared by electrochemical reduction of ordinary polyaniline in organic solvents. The flexibility is directly related to the polymer morphology which was definitely affected by the nature of electrolyte anion. Perchlorate or tetrafluoroborate anion were found suitable to obtain flexible polyaniline. At the same time, it is essential that the polymer so prepared should be reduced (undoped) in some suitable organic solvents before making a flexible free standing film. (Edited author abstract) 11 refs.

**079948 PHYSICAL AND DYNAMIC MECHANICAL PROPERTIES OF UNTRADRAWN POLYPROPYLENE FILMS.** Dynamic mechanical measurements were made on gel films of high molecular weight polypropylene prepared by gelation/crystallization from 1% (w/v) decalin solutions. The measurements were performed at different frequencies in the temperature range from -160°C to the melting point of the sample. The dry gel films were uniaxially drawn at 150°C to various draw ratios ( $\lambda$ ) between 6.5 and 48. The morphology and orientation of the samples were characterized by density, differential scanning calorimetry, infrared dichroism, wide-angle X-ray diffraction, small-angle light scattering, scanning electron microscopy, and dynamic storage modulus. WAXS studies showed that very high degrees of orientation were achieved at the higher draw ratios. (Edited author abstract) 23 refs.

Roy, S.K. (McGill Univ, Montreal, Que, Can); Kyu, T.; Manley, R. St. John. *Macromolecules* v 21 n 2 Feb 1988 p 499-504.

**079949 MECHANICAL RELAXATIONS OF ORIENTED GELATION-CRYSTALLIZED POLYETHYLENE FILMS.** The mechanical relaxations of oriented gelation-crystallized films of ultrahigh molecular weight polyethylene have been studied by dynamic mechanical measurements, in comparison with the behavior of undrawn melt-crystallized specimens. The absence of the  $\gamma$  relaxation in highly drawn gelation-crystallized samples indirectly suggests that the  $\gamma$  process may be related to the local motions of the chain segments located in the amorphous or crystal defective regions. The  $\alpha$  relaxation

in the gelation-crystallized samples is sharper as compared with that in the melt-crystallized sample. (Edited author abstract) 45 refs.

Roy, S.K. (McGill Univ, Montreal, Que, Can); Kyu, T.; Manley, R. St. John. *Macromolecules* v 21 n 6 Jun 1988 p 1741-1746.

**079950 NEW DIRECTIONS IN HIGH PERFORMANCE FILMS.** In the last few years, a growing number of high-performance resins have been made available in film form for a growing number of specialty applications. These applications generally require materials with high thermal and dimensional stability, broad chemical resistance, and an overall high balance of mechanical properties. Commercial high-performance films include hundreds of varieties of polyesters, scores of fluoropolymers, and a large number of polyimides. Polyurethanes, nylons, polycarbonates and alloys are also establishing wider acceptance. Polyetherimide, polyethersulfone, polyetheretherketone, and other exotic resins are also providing imaginative answers to engineering dilemmas. This article discusses valuable materials and applications.

English, Lawrence (Materials Engineering, Cleveland, OH, USA). *Mater Eng (Cleveland)* v 105 n 7 Jul 1988 p 43-47.

**079951 THERMAL AND DYNAMIC MECHANICAL PROPERTIES OF HYDROXYPROPYL CELLULOSE FILMS.** Differential scanning calorimetry (DSC) and dynamic mechanical thermal analysis (DMTA) were used to characterize the morphology of solvent cast hydroxypropyl cellulose (HPC) films. DSC results were indicative of a semicrystalline material with a melt at 220°C and a glass transition at 19°C ( $T_g$ ), although an additional event was suggested by a baseline inflection at about 80°C ( $T_2$ ). Corresponding relaxations were found by DMTA. A secondary relaxation at -55°C was attributed to the interaction between hydroxyl groups of the polymer and residual diluent. (Edited author abstract). 24 Refs.

**079953 STUDIUM RAZOVE HOUZEVNATOSTI RADIACNE SITOVANEHO ROZVETVENEHO PE TYPU BRALEN.** [Impact Strength of Electron Beam Crosslinked BRALEN Low Density Polyethylene.] A low density polyethylene film was crosslinked by electron beam technique. The film properties were found to differ considerably from those of the original unmodified film when dynamically stressed. With respect to service performance of the irradiation crosslinked film, a marked increase in biaxial impact strength, abrasion resistance and - as apparent from the equilibrium elasticity modulus data - a significant dimensional stability at increased temperatures can be considered as major changes of the film properties. A negative effect - faster ageing - is compensated entirely by much faster growth in biaxial impact strength. (Author abstract). 19 Refs. In Czech.

## Metallizing

**079955 METALLIZED OPP FILM, SURFACE CHARACTERISTICS AND PHYSICAL PROPERTIES.** Metallized OPP (oriented polypropylene) film offers exceptional gas and water vapor barrier properties, making it one of the most cost-effective flexible protective packaging materials. Its barrier properties correlate with opacity, which, in turn, depends on the degree of coverage by the metallization. Minor defects, such as scratches, will generally represent only a small percentage of the total coverage of a package and have a proportionally small effect on the barrier properties of the package. The high-energy metal surface is extremely active and will wet well and adhere strongly when clean. In fact, it is so active that it is easily coated with trace amounts of any energy organic material with which it makes contact. For assurance of consistent wetting and bonding, metallized OPP surfaces should be cleaned in-line, such as by bare-roll corona treatment. (Author abstract) 5 refs.

Marra, J.V. (Hercules Inc, Wilmington, DE, USA). *J Plast Film Sheeting* v 4 n 1 Jan 1988 p 27-34.

**079956 INDUSTRIAL APPLICATIONS FOR SUBSTRATES OF METALLIZED FILM.** Twenty years ago, the primary uses for metallized films were in capacitors, metallic yarn and many decorative uses. During the past five years, the market for metallized films in industrial uses has experienced significant growth due to the demand for materials that satisfy requirements such as: (1) thin and lightweight; (2) specialized properties (static dissipation, light screening, reflection); (3) multi-functional properties; (4) high quality maintained within tight specifications; and (5) cost effectiveness. Broad markets have been identified and satisfied with metallized substrates because they are (a) an acceptable alternative or replacement for traditional materials; (b) able to satisfy advances in industrial technology which require performance and/or properties not available in conventional materials. These markets include electronics, automobiles, specialized industrial packaging, aerospace, reprographics and instant photography. 2 refs.

**Microscopic Examination** See Also POLYESTERS—Morphology; POLYMERS—Conductive.

**079957 COMPLEXITIES IN STEM ANALYSES OF POLYMER BLEND THIN FILMS.** Polystyrene (PS)-polyether sulphone (PES) polymer blend thin films were prepared for examination in a scanning transmission electron microscope. The microstructures observed in 75 wt% PS-25 wt% PES films consisted of spherical inclusions, ranging from 0.2 to 1.2  $\mu\text{m}$  in diameter. X-ray spectrometric analysis in the microscope revealed that the inclusions were PES-rich, while the matrix contained only PS. Attention is paid to the contrast in the annular dark field detection (ADF) images from these films. This image contrast has a complicated dependence on both the angular range subtended by the dark field detector and mass thickness variations within the films. On microscopes with lens controls which permit the acceptance

angle of the ADF detector to be varied, it becomes possible to reverse the contrast between the two phases. (Author abstract) 16 refs.

**079958 EFFECTS OF PRESSURE AND SOLVENT ON THE DIFFUSION OF AROMATIC COMPOUNDS THROUGH POLYMERS.** The diffusion of six azo and five anthraquinone derivatives through nylon 6, poly(ethylene terephthalate) and secondary cellulose acetate films were studied under high hydrostatic pressures of up to 3000 bar and at temperatures 80-130°C, by analyzing the diffusion profiles yielded in a stacked multiple film, placed in the solution of the diffusant. It was found that the diffusion coefficient,  $D$ , of the diffusant decreased with increasing pressure, giving a linear relationship between  $\ln D$  and the pressure, the slope of which gave the activation volume for the diffusion. (Edited author abstract) 35 refs.

**079959 PHOTOPHYSICAL STUDIES OF MOLECULAR MOBILITY IN POLYMER FILMS. OXYGEN MOBILITY IN POLYMER FILMS MONITORED BY QUENCHING OF THE TRIPLE-TRIPLET ABSORPTION OF BROMOPYRENE.** Oxygen mobility in several polymer films has been monitored by measuring oxygen quenching of the excited triplet state of film-incorporated bromopyrene observed via its triplet-triplet ( $T_1-T_n$ ) absorption. Cross-linking did not impose any restriction on oxygen movement in the SU8 epoxy film below the glass transition temperature, and the oxygen quenching rate increases markedly with temperature in an uncured epoxy film; the effect is relatively small in a completely cross-linked film. A significant effect of polymer chain structure on the oxygen quenching rate was observed and a possible mechanism discussed. It is found that quenching rate constants are much higher than that expected from the bulk macroviscosity of the film and are of the order  $10^6-10^9 \text{ M}^{-1} \text{ s}^{-1}$ . (Edited author abstract). 21 Refs.

Chu, Deh Ying (Univ of Notre Dame, Notre Dame, IN, USA); Thomas, J.K.; Kuczynski, J. *Macromolecules* v 21 n 7 Jul 1988 p 2094-2100.

**079960 EFFECT OF SUBSTRATES ON THE STRUCTURE OF POLYMER INTERPHASES.** Infrared spectroscopy was used to determine the effect that metal substrates such as titanium, iron, 1100-series aluminum, 2024 aluminum, and copper have on the molecular structure and properties of  $\gamma$ -aminopropyltriethoxysilane ( $\gamma$ -APS) primer films. When  $\gamma$ -APS was adsorbed onto any of the substrates from aqueous solutions at pH 10.4 for 1 min and then dried at room temperature for 30 min, the molecular structure of the primer films was similar and consisted of low-molecular-weight siloxane polymers containing a considerable amount of absorbed carbon dioxide in the form of amine bicarbonates. After the films were dried at elevated temperatures, the structures differed significantly. The reaction of primer films on iron and 2024 aluminum with epoxy resins at 75°C was slow because the temperature was too low for dissociation of the bicarbonates to occur. At 150°C, epoxies reacted readily with  $\gamma$ -APS films on iron but not with those on

2024 aluminum. For primer films on 2024 aluminum, the preferred reaction at 150°C was oxidation of the amino groups. (Edited author abstract). 17 Refs.

**079961 MOLECULAR ORGANISATION OF ELECTROCHEMICALLY PREPARED CONDUCTING POLYPYRROLE FILMS.** Molecular structure-preparation condition relationships are reported for electrochemically prepared polypyrrole-toluene sulphate electrically conducting films. Polypyrrole films have been prepared from aqueous solutions employing a range of anodic potentials (0.5-1.6 V versus SCE) and at several temperatures. Consistently films grown using higher potentials and at lower temperatures exhibited greater electrical conductivities. The molecular organization in these series of films was evaluated using quantitative x-ray scattering procedures. The x-ray scattering data show that polypyrrole molecules adopt a planar-type conformation in which the planes of the pyrrole moieties have a preferred orientation with respect to the electrode surface. This anisotropy is enhanced in samples prepared at low temperatures or at high anodic potentials, and such anisotropic films have greater electrical conductivity. Structural mechanisms for these observations are discussed. (Author abstract) 27 refs.

**079962 MORPHOLOGY OF COMPOSITE FILM PREPARED BY POLYMERIZING STYRENE IN POLY(VINYL CHLORIDE) FILM.** Styrene and the styrene-additive mixtures (kerosene, dioxane, ethylene dichloride, or diethylphthalate) were soaked into a poly(vinylchloride) film and then styrene was polymerized. Subsequently, poly(styrene) was extracted with  $\text{CCl}_4$  and the microporous membrane was obtained, of which the morphology was studied. It is elucidated that the additives affect the morphology of the resultant composite films. (Author abstract). 9 Refs.

**079963 ORIENTATION AND SECOND HARMONIC GENERATION IN DOPED POLYSTYRENE AND POLY(METHYL METHACRYLATE) FILMS.** Glassy polymers such as polystyrene (PS) and poly(methyl methacrylate) (PMMA) doped with optically characterized second harmonic generating dyes were examined for their nonlinear optical properties as determined by sample treatment and physical aging. The authors results can be related to the mobility in the polymer films and free volume theory for physical aging in polymer glasses. When secondary relaxations, associated with limited molecular mobility, are considered for PMMA and PS, it is seen that at room temperature the mobility of PMMA should be much greater due to the greater mobility of the acrylate side chain on the PMMA. Even though both polymers have glass transition temperatures at about 100°C or slightly above, the broad secondary transition for PMMA occurs between about -50 and -30°C and for PS at about 35-50°C. 14 refs.

## Performance

**079964 PREDICTING THE PERFORMANCE OF LINEAR LOW-DENSITY POLYETHYLENE BLOWN FILM.** Producers of polyethylene film and resin are continually challenged to improve product performance. Several molecular characteristics of LLDPE affect the performance of films: molecular weight, molecular weight distribution, density, comonomer type, and the distribution of the comonomer along a single chain and among all chains. Blown film properties are generally improved by increasing molecular weight, narrowing molecular weight distribution, and narrowing short-chain branching distribution. 11 refs.

**Permeability** See Also FOOD PRODUCTS—Packaging; POLYAMIDES—Film; POLYESTERS—Modification.

**079965 TRANSPORT OF ETHYLENE OXIDE THROUGH POLYMER FILMS.** The transport of gaseous ethylene oxide (EtO) in several polymer films is studied using the carrier gas method of measurement. Permeability, solubility, and diffusion coefficients describing ethylene oxide (EtO) transport in polypropylene, polyvinylchloride, Teflon-FEP copolymer, and polyethylene films have been obtained over a 30 Celsius degree range at a low concentration of EtO using the carrier gas method of measurement. The results indicate that the diffusion of EtO in polyethylene is independent of penetrant concentration over the range of concentrations used. However, concentration-independent diffusion could not be verified directly for the other films studied. Two different techniques of determining diffusion coefficients were used, and within the precision of the data both yield the same result. An excess enthalpy of solution for the solubility of EtO in Teflon-FEP copolymer was calculated, an observation that suggests that dual-mode sorption may be taking place. (Author abstract) 45 refs.

**079966 GAS PERMEABILITY MEASUREMENTS ON SCREENED EVACUATED INSULATION BASED ON PERFORATED SCREENS.** One can reduce the gas pressures in screened evacuated insulation (SEI) by the use of perforated diffraction screens (PDS). However, difficulties in manufacturing technology have limited their use. A possible way of improving SEI is to optimize the basic parameters of the perforated screens to bring the gas permeabilities up to the level of PDS. We have examined the transverse gas permeability in SEI containing perforated screens and various inserts as affected by the diameter of the holes (at constant screen porosity) and by the porosity (for a fixed hole diameter). It is shown that the screen perforation parameters influence the transverse gas permeability of the insulation under molecular-flow conditions. (Edited author abstract) 6 refs.

## Permeability, Mechanical

**079967 GAS PERMEABILITY OF PLASMA POLYMERIZED FILMS PREPARED FROM VARIOUS ORGANOSILIC COMPOUNDS.** In order to examine the effect of monomers on the gas permeability of plasma polymerized films, five kinds of organosilic compounds (tetramethylsilane and the derivatives substituted by ethoxy groups) were used as the monomer, and plasma polymerized films were deposited on porous substrates. The gas permeability and IR spectra were measured. It was found that each plasma-polymerized film retained the chemical structures of the associated mono-

mers. The ratio of oxygen to nitrogen permeation rates decreased with increasing the numbers of the substituted ethoxy groups. The membrane prepared from the monomer in which two ethoxy groups were substituted showed the highest value of the oxygen permeation rate. (Edited author abstract). 8 Refs. In Japanese.

**079968 ANNEALING EFFECT ON CHEMICAL STRUCTURE AND PHYSICAL PROPERTIES OF PLASMA-POLYMERIZED TRIETHYLINDIUM.** Annealing effect on chemical structure and physical properties of thin films, prepared by r.f. glow discharge of triethylindium (TEI), was investigated. The film, as deposited, contained mostly hydrocarbon, and the appearance was dark brown and opaque. The structure of the film was amorphous. On annealing in air, hydrocarbon contents in the film decreased, oxygen contents increased, and the crystallization progressed. The appearance of the film changed from opaque to transparent, and the electrical conductivity increased by annealing. (Edited author abstract). In Japanese. 19 refs.

**079969 EXPANSION COEFFICIENTS IN AVERAGING FOURTH-RANK TENSORS IN TERMS OF JACOBI'S POLYNOMIALS.** Some physical quantities, such as elastic constant (or compliance) and intensities of polarized fluorescent light and laser-Raman scattering light passed through anisotropic polymer films, are governed by the results of space-averaging weighting with the molecular distribution function  $\omega(\cos \theta, \phi, \eta)$  of the fourth rank tensor  $T_{ijkl}$  defined by a coordinate transformation of a fourth rank tensor. Some of the expansion coefficients of  $T_{ijkl}$  disappear due to the nature of symmetry in the sample. As proposed by Morris, the non-expansion coefficients remain only for the samples with symmetry higher than or equal to that of an orthogonal system. In the general case, which is represented by triclinic system, there can be imaginary parts in the remaining coefficients; these are classified into seven groups. These coefficients induced from generalization are important for evaluating molecular orientation. (Edited author abstract) 14 refs. In Japanese.

**079970 KINETICS OF RECOVERY OF BIAXIALLY ORIENTED STYRENE-ACRYLONITRILE COPOLYMER FILMS.** Styrene-acrylonitrile copolymers were biaxially oriented to obtain a draw ratio of about 6.9 in the machine direction (length) and 2.9 in the transverse direction (width). The prepared films, 28  $\mu\text{m}$  thick, were annealed at elevated temperatures for different time periods. The length and width of the film gradually decreased, accompanied by an increase of the film thickness during recovery. The variations of the film length, width and area with time were all found to follow second-order kinetics for the later part of the recovery process. The arrhenius plots of the rate constants showed activation enthalpies in the range from 120 to 127 kcal  $\text{mol}^{-1}$ . Based on these observations, the kinetics of volume recovery were also shown to be second-order at long recovery times. (Edited author abstract) 19 refs.

**079971 SURFACE TENSIONS AND STRUCTURES OF ACRYLIC BASE FILMS EB-GRAFTED WITH METHYL METHACRYLATE.** Mixtures of acrylates were cured by electron beams. Surface tensions of those acrylic base films were controlled by changing the mixing ratio of acrylates. The grafting was carried out by coating methyl methacrylate on the base film and irradiating with electron beams. It is assumed that the grafting side chains (poly(methyl methacrylate)) exist on the base film as nearly mono-molecular layers, and that those conformations were arranged by the interaction between the base film and the grafting side chain. The conclusion is that the covering ratio of the grafting side chains on the base films was controlled to minimize interfacial tensions against the base films during the graft-polymerization. (Edited author abstract) In Japanese. 14 refs.

**079972 POLYMERIC MOTIONS DETECTED BY WETTING MEASUREMENTS AT THE FILM/WATER INTERFACE AS INFLUENCED BY CONFORMATIONAL CHANGES AT THE FILM/SUBSTRATE INTERFACE.** This research was concerned with examining the conformational changes that a solvent produces upon a thin polymeric film. The solvent of choice was water, as it is especially indicative of the changes that occur in biological systems and water-borne coatings systems. The intent was to characterize the rates at which these conformational changes occurred, by measuring the time the water took to pass from the surface of the film to a substrate. To obtain the parameters for the characterization, contact angle and ultrasonic measurements were made. The contact angle measurements provided information on the interactions taking place at the film/air interface. The ultrasonics, on the other hand, provided a measure of the interactions that occurred at the film/substrate interface. This paper presents the theory behind the measurements that were made, as well as the manner in which the various measurements were made. It also provides insight into alternate methods for collecting the data which can be of use in future research. The information collected is then used to draw conclusions about the interactions that actually were detected in the films tested. These interactions are then related to the conformational phenomena previously mentioned and the mode of penetration is also discussed. (Author abstract) 16 refs.

**079973 ORIENTATION DISTRIBUTION FUNCTION IN CRYSTALLITES OF ROLLED POLYPROPYLENE AND POLY(VINYL ALCOHOL) FILMS.** A new evaluation method of the crystalline orientation distribution function is proposed. It uses the model that the lamella axis is taken as one of the principal axes in the crystalline block and that the slippages are introduced by the maximum shear direction, and that the intra-lamella slip is around the transverse direction. We applied this method to the rolled polypropylene film, and compared the results with the observed pole figures. We also discussed the orientation distribution functions of the rolled poly(vinyl alcohol) films, using the evaluating method of the orientation distribution functions applied to the bi-axially stretched PVA films. (Edited author abstract) 8 refs. In Japanese.

**079975 PRODUCTION AND CHARACTERIZATION OF HOMOGENEOUS POROUS POLYMER FILMS.** The development of a simple and reproducible production method for thin homogeneous polymeric films is reported. By a special process, highly swollen films can be manufactured without dimensional changes as known from normal swelling processes. With regard to using these films as well-defined active layers in composite membranes, they were characterized by measuring the water flux, the salt rejection and the molecular weight cut-off. The results lead to a very useful correlation between production parameters and membrane performance. (Edited author abstract)

**079976 POSTIRRADIATION DIFFUSION OF OXYGEN INTO IRRADIATED DOSIMETRIC POLYMER FILMS.** The authors studied the influence of  $^{60}\text{Co}$  gamma radiation on the oxygen permeability both of prepared dosimetric compositions based on polyvinyl chloride (PVC) and on polymers promising for dosimetric purposes: polycarbonate (PC), aliphatic polyamide with addition of an azo dye (PA), polyarylene sulfone (PSF), and polyvinyl chloride with addition of various organic dyes. The results show that irradiation of PSF and PVC produces a sharp increase of the solubility of oxygen. In the case of PVC a dose of 0.12 MGy increases  $\sigma$  by a factor of over 30. On the other hand, in the case of PA irradiation results in decrease of  $\sigma$  for  $\text{O}_2$ . In pure PA oxygen permeability was not detected even after a dose of 0.03 MGy, while in PA with addition of the azo dye  $\sigma$  decreased by a factor of 70 after a dose of 0.05 MGy. It is found that the change of oxygen solubility corresponds to the magnitude of the post effect in irradiated polymers. 5 refs.

**079977 WAXES AND SACS INVESTIGATION OF THE SUPERMOLECULAR STRUCTURE OF LDPE FILMS IRRADIATED WITH FAST ELECTRONS.** Low-density polyethylene (LDPE) films irradiated with fast electrons within the range of irradiation doses 9-40 Mrad have been studied by means of WAXS and SAXS. The degree of crystallinity, the total intensity of WAXS, and the dimension of the mosaic blocks in the [110] and [200] directions have been found to be almost independent of the irradiation dose. The SACS parameters (long period, lamella thickness, intensity of scattering from the diffuse and the discrete regions, total intensity) depend on the dose in the same way. A parallel has been made between the x-ray and the calorimetric degree of crystal-

linity. The latter shows a threefold greater decrease with the increase of the dose, in comparison with the former. (Edited author abstract) 18 refs.

**079978 EFFECT OF DIVINYLSULFONE ON THE IRRADIATION CROSSLINKING OF POLYPROPYLENE.** Polypropylene films were irradiated with  $^{60}\text{Co}$   $\gamma$ -rays in divinylsulfone (DVS) or butadiene (BD) gases. The variations of the intrinsic viscosities of the samples irradiated in vacuum or in DVS with dose showed usual patterns but the variation of the latter was somewhat more rapid. The intrinsic viscosity of the sample irradiated in BD could not be measured due to the early appearance of gel. The gel fraction of the sample irradiated in DVS appeared at lower dose than that irradiated in vacuum, but the former did not increase as much as the latter. The gel fraction of the sample irradiated in BD increased remarkably. The concentrations of the two kinds of double bonds increased in the sample irradiated in BD but levelled off gradually with dose. (Edited author abstract). 11 Refs.

**079979 RADIATION EFFECT OF A HIGH ENERGY ELECTRON BEAM ON THIN FILMS OF SATURATED AND UNSATURATED FATTY ACIDS.** Studies have been carried out on electron beam induced polymerization of LB (Langmuir-Blodgett) films of saturated and unsaturated long chain aliphatic acids, in an attempt to obtain information about the dose dependence of conversion in relation to molecular arrangement. The results indicate that polymerization of unsaturated aliphatic acid LB films occurred when irradiation was carried out in a nitrogen atmosphere and that the LB films of a disordered state are more sensitive to radiation than tightly packed LB films. (Edited author abstract). 10 Refs.

**079980 CHARACTERIZATION OF ELECTRON-IRRADIATED BIAXIALLY-ORIENTED POLYPROPYLENE FILMS.** Post-radiation changes in the electrical and mechanical properties of capacitor-grade isotactic polypropylene films exposed to electron radiation were previously reported by the authors (1987). Based on the data obtained, it was suggested that crosslinking, chain scission and oxidative degradation were responsible for the radiation-induced changes in the film. In the present investigations, additional electrical characterizations that included the DC breakdown voltage and AC conductivity measurements were performed. Effects of the electron radiation on the physical and chemical properties were also evaluated to identify the actual degradation mechanisms. These studies included scanning electron microscopy, X-ray diffraction, infrared spectroscopy and sol-gel measurements. The results obtained confirm that crosslinking and chain scission of the polymer are responsible for the changes in the lower dose range, whereas oxidative degradation becomes predominant at higher dose levels. 11 refs.

## Research

**079981 INTERPRETATION OF POLYAZULENE ELECTROPOLYMERIZATION CONSIDERING FARADAIC CURRENT EFFICIENCY AND CAPACITIVE CURRENT EFFECTS DURING THE GROWTH AND REDOX SWITCHING STEPS.** A theoretical analysis of the electropolymerization of azulene at a rotating ring-disk electrode is presented. This analysis provides a method for determining the current

efficiency of electropolymerization. The oxidation of azulene to polyazulene in acetonitrile as solvent is a convective-diffusion controlled process that proceeds with 100% current efficiency. A positively charged site is associated with at least two non-terminal monomer units in the oxidized form of the polymer. Hydrogen ion has been identified and quantitated as a product of the electropolymerization process. No hydrogen ions are produced by the redox process involving only the polymer film. (Edited author abstract) 14 refs.

**079982 SURFACE STUDIES OF POLYMER FILMS AND FIBERS BY CIRCLE ATR FT-IR.** The advantages of the CIRCLE ATR technique for the study of films and fibers make it a simple, nondestructive method with which a good signal-to-noise ratio can be obtained. The latter is mainly due to the longer pathlength and larger effective surface area of the CIRCLE ATR element. Applications include the ability to analyze flexible materials, especially fibers which are difficult to analyze using rectangular ATR. Optical properties, such as refractive index and absorption index as a function of wavelength, can also be determined with the use of previously reported methods. 11 refs.

**079984 MONOLAYER AND LANGMUIR-BLODGETT MULTILAYER SURFACE AND SPECTRAL STUDIES OF POLY-3-BCMU.** Monolayer films of poly-3-BCMU are shown to form at the air-water interface, the surface pressure/area per residue ( $\pi/A$ ) isotherms of which exhibit a horizontal plateau indicative of a phase change occurring on compression. Langmuir-Blodgett monolayer films, transferred while proceeding through this region, have visible absorption spectra indicating a conformational change from an amphipathic yellow to a nonamphipathic blue form having increased  $\pi$ -electron conjugation. A thermodynamic analysis of the temperature dependency of the compressional onset of the plateau ( $\pi_c$ ), interpreted in terms of a corrected two-dimensional analogue of the Clapeyron equation, shows a slightly exothermic transition. A comparison of isotherms obtained both by continuous compression and by a stepwise 'equilibrium' method shows considerable relaxation can take place at areas per residue less than 100 Å<sup>2</sup>. This is interpreted as reflecting the pronounced reorganization required for the highly ordered blue conformation to completely form. (Edited author abstract) 7 refs.

**079985 SPECTROELECTROCHEMICAL STUDY OF THE ELECTRODEPOSITION OF POLYTHIOPHENE FILMS.** The growth of polythiophene films has been studied using time resolved in situ transmission spectroscopy in the wavelength range 350-820 nm. Several distinct stages to the polymerisation process have been identified. In the first of these, a small quantity of intermediates, which we suggest might be short chain oligomers, was observed. At slightly longer times, which a previous electrochemically based analysis associated with the expansion of growth sites, the absorbance shifted to longer wavelengths. Finally, features normally considered to be characteristic of the 'metallic' form of the polymer predominate. Correlation of spectroscopic and electrochemical data showed these clearly, together with more subtle changes occurring in thicker films which were not apparent from the electrochemical data alone. Absorbance vs. charge plots were used to estimate optical parameters for growing films: while we found no evidence for a potential dependence of these parameters in the range 1.80-1.95 V, the values were different from those obtained at high potentials. (Author abstract) 28 refs.

**079987 MICROSTRUCTURES AND THEIR ORIENTATION BEHAVIOR IN A THERMOTROPIC POLYESTER.** Microstructures and their orientation behavior in quenched films of a thermotropic polyester, poly(chloro-1,4-phenylene-trans-1,4-cyclohexanedicarboxylate), were studied by electron microscopy, polarized-light microscopy, and x-ray diffraction. Oriented films were obtained by shearing the anisotropic melt of the polymer and cooling to 0°C. Fibrous structures shaped like ribbons or prisms were observed in fractured lateral surfaces of quenched films. Prismlike fibrils are composed of ribbonlike fibrils, the thickness of which is less than 0.1  $\mu\text{m}$ . Streaks suggesting the end of ribbonlike fibrils were observed on the surface of fibrils. (Edited author abstract) 12 refs.

**079988 STRUCTURE OF BLOWN PE FILM GOES WITH THE RESIN'S FLOW.** During the blowing process polymer melt is subject to stresses that are the combined result of the blowing conditions and the rheology of the resin. Thus it is the melt's thermomechanical history that determines the morphology and orientation of the crystalline and amorphous phases. This study characterized the structure and properties of tubular blown polyethylene films processed under a variety of conditions. The morphology of the film is explained on the basis of the rheological properties of the resin and its stresses during processing.

**079991 STUDY OF THE TEMPERATURE-TIME INFLUENCE ON THE PROCESS OF STRUCTURING IN NON-ORIENTED FILMS OF POLY(4,4'-OXYDIPHENYLENE)PYROMELLITIMIDE.** IR spectroscopic, X-ray and dilatometric methods have been employed to study the influence of the rate of heating and the end temperature of thermal treatment of the samples on the process of structuring and the parameters of the structure formed in non-oriented films of poly(4,4'-oxydiphenylene)pyromellitimide. The observed effect of self-elongation is a consequence of the structural rearrangements occurring on heating the samples above the softening point. The degree of ordering rises with the increase in the end temperature of thermal treatment and the heating rate. (Author abstract) 16 refs.

**079992 SPECTROELECTROCHEMICAL STUDIES OF POLYANILINE.** The structural change and electrode reaction mechanism of polyaniline with counter anion  $\text{NO}_3^-$  were investigated on the basis of vis-n.i.r. absorption spectra at different potentials in 1 M  $\text{NaNO}_3$  aqueous solution at pH 1.5, with and without alkali treatment of the polyaniline film. Three redox stages were found in the spectra and the cyclic voltammogram in the potential range -0.4 V to 0.8 V (versus SCE). The equilibrium electrode potential of as-prepared polyaniline film is  $\approx 0.3$  V (versus SCE) in 1 M  $\text{NaNO}_3$  aqueous solution at pH 1.5 (Edited author abstract). 9 refs.

**079993 TEORIE ZJAWISK WYSTĘPUJĄCYCH W WARSTWIE GRANICZNEJ FOLIŹ POLIOLEFIN I FARBŹ DUKARSKIEJ.** [Theory of Phenomena Oc-

curing in the Polyolefin Film/Printing Ink Interface Layer]. The principal methods of surface treatment of polyolefin (PE, PP) films have been presented and the difficulties connected with the explanation of phenomena occurring during this treatment pointed out. A critical review of theory concerned with the interpretation of physical and chemical phenomena in the polyolefin film/printing ink interface layer has been given. The main obstacles preventing the elaboration of a uniform theory common for all these phenomena have been discussed and differences encountered in the interpretation of some facts presented. An evaluation of the individual theories from the point of their practical utilization has been attempted. (Edited author abstract) In Polish. 30 refs.

**079994 MICROANALYSIS OF POLYMERS USING A WINDOWLESS ENERGY-DISPERSIVE X-RAY DETECTOR.** The surface compositions of various polymeric films, grown electrochemically on platinum foils, have been investigated by energy-dispersive x-ray analysis in conjunction with scanning electron microscopy (SEM/EDS). Comparison of the relative area ratios of peaks for the C and N  $K_{\alpha}$  emission lines show that the EDS may be used to study the surface composition of polymers. The evidence presented strongly suggests that there is a limited structural degradation and the elemental composition is not changed under the electron beam at relatively low accelerating voltages. This technique statistically samples the repeat units of the polymer. For samples grown in both aqueous and nonaqueous solutions. SEM/EDS provides evidence for extensive contamination with oxygen. (Author abstract) 15 refs.

**079996 STUDY ON ROUGH-SURFACE BIAXIALLY ORIENTED POLYPROPYLENE FILM. I. FORMATION OF  $\beta$ -FORM CRYSTALS IN SHEET CAST WITH T-DIE EXTRUDER.** Sheets were cast by extruding polypropylenes (PP) which contained  $\gamma$ -quinacridone, a  $\beta$ -crystal nucleator, at levels of 0-10 ppm using a 30 mm  $\phi$  extruder with a T-die at extrusion temperatures of 200-260°C and chill roll temperatures of 30-90°C. The influences of raw resin characteristics such as  $\gamma$ -quinacridone content and MFI of the base PP and casting conditions such as extrusion temperature and chill roll temperature on the amount of  $\beta$ -crystals formed in the sheet were studied. The amount of the  $\beta$ -crystals formed was larger as the  $\gamma$ -quinacridone content was higher and the extrusion temperature was lower and almost independent of the chill roll temperature. (Edited author abstract) 57 Refs.

**079997 STUDY ON ROUGH-SURFACE BIAXIALLY ORIENTED POLYPROPYLENE FILM. II. INFLUENCE OF STRETCHING CONDITIONS.** The production of rough-surface biaxially oriented polypropylene film (BOP) has been studied by means of casting a polypropylene which contained  $\gamma$ -quinacridone, a  $\beta$ -crystal nucleator, with a T-die extruder into a sheet which has subsequently been stretched successively in the machine direction (MD) and the transverse direction (TD) with a roll-type stretching machine and a pantograph-type stretching machine, respectively. For roughening of BOP using  $\beta$ -form crystals in a successively stretching tenter method, it is preferable to roughen in the MD-stretching process, with suppression of the recrystallization into the  $\alpha$  crystals after melting of the  $\beta$  crystals being the most important objective. (Edited author abstract) 20 Refs.

Fujiyama, Mitsuyoshi (Tokuyama Soda Co, Tokuyama, Jpn); Kawamura, Yoshimasa; Wakino, Tetsuo; Okamoto, Tomomi. *J Appl Polym Sci* v 36 n 5 Aug 20 1988 p 995-1009.

**079998 STUDY ON ROUGH-SURFACE BIAXIALLY ORIENTED POLYPROPYLENE FILM. III. INFLUENCE OF MFI OF BASE RESIN.** The influences of melt flow index (MFI) of base polypropylene (PP) and machine and transverse direction stretching conditions on the roughening of BOP have been studied. Rough-surface BOPs were obtained by casting homoisotactic PPs, having MFIs of 1.3-9.8 dg/min and containing no  $\beta$ -crystal nucleator, with a T-die extruder into sheets which subsequently have been stretched successively in the machine direction (MD) and the transverse direction (TD) with a roll-type stretching machine and a pantograph-type stretching machine, respectively. The level of  $\beta$ -crystal content in the cast sheet was maximum when a PP with MFI = 8 dg/min was used as a raw material and the obtained roughness state of the BOP was the best. (Edited author abstract) 4 Refs.

Fujiyama, Mitsuyoshi (Tokuyama Soda Co, Tokuyama, Jpn); Kawamura, Yoshimasa; Wakino, Tetsuo; Okamoto, Tomomi. *J Appl Polym Sci* v 36 n 5 Aug 20 1988 p 1011-1023.

**079999 STUDY ON ROUGH-SURFACE BIAXIALLY ORIENTED POLYPROPYLENE FILM IV. INFLUENCE OF ADDITION OF CRYSTAL NUCLEATOR.** In the roughening of biaxially oriented polypropylene film (BOP) by utilizing  $\beta$ -form crystals in a successively stretching tenter method, the influence of an  $\alpha$ -crystal or  $\beta$ -crystal nucleator added to base polypropylene (PP) during roughening of BOP has been studied. Rough-surface BOPs were made from homoisotactic PPs which had a melt flow index (MFI) of 8.5 dg/min and contained the  $\alpha$  or  $\beta$  nucleator at levels of 0-10 ppm. The  $\beta$  crystals formed in cast sheets and the roughness of the BOPs were analyzed. Degree of roughness and the diameter of craters on BOP decreased with increasing  $\alpha$ - or  $\beta$ -nucleator content. This stems from the fact that the diameter of the  $\beta$  spherulites formed in the cast sheet decreases with increasing nucleator content. (Edited author abstract) 4 Refs.

Fujiyama, Mitsuyoshi (Tokuyama Soda Co, Tokuyama, Jpn); Kawamura, Yoshimasa; Wakino, Tetsuo; Okamoto, Tomomi. *J Appl Polym Sci* v 36 n 5 Aug 20 1988 p 1025-1034.

**080000 STUDY ON ROUGH-SURFACE BIAXIALLY ORIENTED POLYPROPYLENE FILM. V. ANALYSIS AND CONTROL OF ROUGHNESS.** The results obtained in the previous studies have been summarized. The roughness can quantitatively be represented by average roughness  $R_a$  (depth of roughness) and roughness period  $L$  (density of roughness).  $R_a$  and  $L$  can largely be changed by changing machine direction (MD)-stretching temperature and the melt flow index (MFI) of base polypropylene (PP), respectively. Furthermore, a BOP with a low roughness period (high density of roughness)

can be obtained by adding crystal nucleators to the base PP. (Edited author abstract) 5 Refs.

Fujiyama, Mitsuyoshi (Tokuyama Soda Co, Tokuyama, Jpn); Kawamura, Yoshimasa; Wakino, Tetsuo; Okamoto, Tomomi. *J Appl Polym Sci* v 36 n 5 Aug 20 1988 p 1035-1048.

**080001 STUDY ON ROUGH-SURFACE BIAXIALLY ORIENTED POLYPROPYLENE FILM. VI. ROUGHENING BY LAMINATED CAST SHEET.** When the roughening of biaxially oriented polypropylene film (BOP) is performed by forming  $\beta$  crystals in a monolayer cast sheet, occasionally voids are formed in the BOP. In order to prevent this and to roughen both sides of the BOP, rough-surface BOPs were obtained by casting two-resin, three-layer sheets consisting of two surface layers with a high-melt flow index (MFI) polypropylene (PP) and a core layer with a low-MFI PP, by stretching the cast sheets five times in the machine direction (MD) with a roll-type stretching machine, and by stretching the MD-stretched sheets 10 times in the transverse direction (TD) with a pantograph-type stretching machine. (Edited author abstract) 7 Refs.

**080002 STUDY ON ROUGH-SURFACE BIAXIALLY ORIENTED POLYPROPYLENE FILM. VII. ROUGHENING BY BLENDING LOW MELTING POINT POLYMERS.** The roughening of biaxially oriented polypropylene film using polypropylene (PP) blended with low melting point polymers such as polybutene-1 and high-density polyethylene as raw resin in a successively stretching tenter method has been studied for the same reasons as has the roughening of BOP utilizing  $\beta$  crystals. Rough-surface BOPs with a low depth and a high density of roughness were obtained by using the blended PPs as raw resins. By combining this roughening method with the roughening method utilizing the  $\beta$  crystals, rough-surface BOPs with a crater-like large roughness and a fine roughness on the ground were obtained. These rough-surface BOPs showed excellent impregnation properties of insulating oils. (Author abstract) 13 Refs.

**080005 THERMAL-AGING BEHAVIOR OF BO-PP FILMS.** The variation in electrical properties and morphology of biaxially-oriented polypropylene (BO-PP) films with thermal aging is discussed, using two kinds of BO-PP films. It was found that the thermal aging behavior of those two types of films depends on their initial morphology. The thermal aging gives rise to an increase in the degree of crystallinity due to crystallization of a part of the amorphous phase in BO-PP films. Crystal reorganization was also indicated, resulting in the improvement of the crystal perfection and the thermal stability. The increase in crystallinity enhances selective morphological change and also selective degradation in the amorphous phase. The morphological change due to the thermal aging manifested itself clearly in dielectric and electrical conduction properties in the form of an increase in primary relaxation loss peak and an increase in ionic conduction loss. 22 refs.

## Thermal Properties

**080006 DSC ANALYSIS OF EB-CURED POLYURETHANE-ACRYLATE.** The gel films obtained by electron beam (EB) solid-state polymerization of urethane-acrylate prepolymers were characterized by differential scanning calorimetry (DSC). Two kinds of urethane-acrylates were synthesized by reaction of poly(butylene adipate)diol (PBAD), 4,4'-diphenylmethane diisocyanate (MDI) and 2-hydroxyethyl acrylate (HEA) for this purpose. One is a semicrystalline prepolymer (UA-251M) with a number average molecular weight ( $M_n$ ) of 3200, and the other is an amorphous one (UA-071M) with  $M_n$  of 1450. The molecular weight between crosslinking junctions was found to be larger than the  $M_n$  of the prepolymer. The crosslinking by the EB polymerization restricted the mobility of the polymer chain less strongly than the crosslinking by the three-functional isocyanate and  $\alpha$ ,  $\phi$ -dihydroxy(polypropylene oxide) with a molecular weight of 1000 did. (Edited author abstract) In Japanese. 16 refs.

## Thick Films

**080007 HIGH FIELD CONDUCTION IN SOLUTION-GROW PVB FILMS.** The dc current characteristics of solution-grown PVB films, studied as a function of voltage (30-1500 V), temperature (303-398 K) and thickness (30-70  $\mu$ m), have revealed two regions of conduction. The region governing the high-field conduction has been attributed to the space charge limited currents. The values of effective drift mobility ( $\mu_e$ ) and trapped charge carrier concentration ( $n_t$ ) which result in the build-up of space charge, have been found to be  $\approx 1.41 \times 10^{-12}$  cm<sup>2</sup>/V-s and  $6.13 \times 10^{14}$  cm<sup>-3</sup>, respectively. (Author abstract). 8 Refs.

## Vapor Deposition

**080008 PLASMA-DEPOSITED METAL-CONTAINING POLYMER FILMS.** The plasma treatment of vapors containing organometallic compounds (of Pd, Ni, Co, Sn, Au) and various alkenes has been used to prepare thin films, the composition and electrical resistivity of which could be varied over a wide range. It is found that the film composition strongly depends on experimental parameters, especially the ratio argon/alkene/organometallic in the gas phase. Since the rates of film formation from organometallics and from alkenes depend differently on temperature, the carbon/metal ratios can easily be controlled by the substrate temperature. With changing elementary composition of the films, their resistivity can be altered from insulating to metallic. (Edited author abstract) 23 refs.

## Wear

**080010 FRICTION AND WEAR OF AN ELECTRICALLY CONDUCTIVE POLYESTER-CARBON FILM.** The friction and wear behavior of an electrically conductive polyester-carbon composite film was examined during dry reciprocating sliding against typical noble and base metal pins. While the frictional force was monitored continuously, the wear volume was determined at the conclusion of each test. The experimental results suggest that the carbon filler acted as an effective solid lubricant during tests against the noble metal pins. However, during tests against the base metal pins at relative humidities above about 40 percent, this lubricating mechanism was impaired, thus resulting in an increase in the friction and wear of the polyester-carbon composite. An adhesive wear mechanism is proposed to account for the observed behavior. (Author abstract). 24 Refs.

## X-Ray Analysis

**080011 CONOSCOPIC AND X-RAY DIFFRACTION STUDY OF THE MOLECULAR AND LAMELLAR ORIENTATION IN LDPE FILMS.** By means of conoscopic and WAXS methods, the type of lamellar orientation in a LDPE blown film has been investigated. The WAXS diffractograms establish the existence of plane-axial texture, the crystallographic axis of the unit cell being predominantly parallel to the machine-processing direction (the M axis) of the film. The conoscopic data indicate that the film as a whole behaves like an optically positive biaxial monocrystal, the plane of the film being a section perpendicular to the obtuse bisectrix. (Edited author abstract) 11 refs.

**080012 DEVELOPMENT OF INTEGRAL SKIN FOAMS BASED ON MODIFIED ISOCYANATE WITH SELF-RELEASING CHARACTERISTICS.** This work describes the development of Integral Skin Foams based on modified isocyanates presenting physical properties superior to those obtained with crude MDI/MDI prepolymers which are the industry standard. Also studied is the incorporation of an IMR (Internal Mold Release) package to developmental formulations in order to minimize the need of an EMR (External Mold Release).

Pauperio, A. (Dow Chemical, Sao Paulo, Brazil); Santos, R.N. *J Cell Plast* v 23 n 5 Sep-Oct 1987 p 448-459.

**080013 AMINE CATALYSIS OF POLYURETHANE FOAMS.** The present catalysis study was confined to model systems. Using a single solvent, at a fixed temperature, with a fixed concentration and isocyanate index over 20 catalysts were characterized. The activity and selectivity of the catalysts toward the urethane and urea reactions were compared. The study is useful to the formulator inasmuch as the rankings of commercial catalyst molecules for their selectivity of the blowing, gelling and trimerization reactions can be transposed to real systems. The experimental data collected in this study and an analysis of the spatial interplay of conventional amine catalysts with isocyanate, water and polyols shows that the separation of the functional centers on a catalyst molecule determines its selectivity and to a lesser extent its activity. 59 refs.

**080014 SOME THERMODYNAMIC OBSERVATIONS ON THE MECHANICAL PROPERTIES OF CUSHIONS.** The adequacy of the assumption that the dynamic behavior of closed-cell, low-density foams under impact may be modeled as trapped air under adiabatic compression is addressed. Using thermal convection coefficients from the literature, certain geometric properties of cushions, and the results for the impact temperature history from the adiabatic model, it is shown that the heat transferred over the duration of the impact exceeds the limit allowed by the first law of thermodynamics. The adiabatic assumption is therefore self-contradictory. A set of coupled thermodynamic relations incorporating heat transfer by convection are then developed for the impact response and used to make some general comments on the nature of cushions under dynamic loading. (Author abstract) 11 refs.

**080015 MATERIALY NA BAZIPLASTU PRO TLUMENI HLUKU A VIBRACI.** [Plastics for Noise and Vibration Control]. For noise and vibration isolation, plastics foams with good relaxation properties are suitable, in which the loss factor and modulus of elasticity can be controlled by compounding. It is evident that poor sound-absorbing materials can act as good sound insulators or sound barriers. Effective acoustic properties can be obtained by optimizing frequency, temperature and character of the polymer system used. It is apparent that the energy absorption capacity of viscoelastic materials drops down markedly at temperatures considerably higher than their glass-transition temperature. The design itself of the isolation system is essential in actual cases of noise and vibration control. A good noise control is achieved when compression and tensile vibrations are converted to shear vibrations. (Author abstract). 73 Refs. In Czech.

**080018 RECOVERY OF CHLOROFLUOROCARBON 11 BY ACTIVATED CARBON SCRUBBING ON A POLYURETHANE FOAM SLABSTOCK PLANT.** Operation of a pilot scale activated carbon CFC 11 recovery unit has been studied. For CFC 11 the trapping efficiency of the scrubber is close to 100% immediately after regeneration, falling to 95% when 12% by weight CFC has been added to the scrubber. About 10-15% of the CFC used by the plant is captured. Recovery is less efficient, due to losses in the condenser, and only 50-60% of the trapped material is obtained for re-use. Examination of this material has shown significant differences from the unused sample, but admixture of recovered with unused CFC has proved successful in plant operations. (Edited author abstract)

Nutt, A.R. (BTR Industries Ltd, Birmingham, Eng); Skidmore, D.W. *Cell Polym* v 6 n 4 1987 p 62-78.

**080019 FOAM PRODUCERS SEARCH FOR NEW BLOWING AGENTS.** Due to rising public pressure and the probability of legislative action, foam producers using fully halogenated chlorofluorocarbons as blowing agents may face cost increases in the near future. Meanwhile, suppliers of blowing agents are scrambling to come up with suitable substitutes for CFC agents as soon as possible. Basically, foam producers are caught in a no-win situation. If they switch to currently available CFC substitutes with lower ozone depletion potential, they will have to pay more for them. If the switch is made to the more flammable hydrocarbons, the manufacturing procedure must be changed to ensure personnel are protected. In addition to CFC substitutes or alternative blowing agents, other action foam producers can take to help deal with the problem include filtering the exhaust so the CFCs do not get into the atmosphere, and recycling CFCs. Industry is unlikely to pursue filtering. The cost for scrubbers and filtering systems is high, and the techniques used are not efficient.

## Deformation

**080021 STIFFNESS OF LIGHTWEIGHT OPEN-POROSITY FOAM PLASTICS.** A previous study proposed one of the first models of the strain properties of lightweight open-porosity foam plastics with a pronounced rod structure. The model is a system of randomly oriented rods, with the elastic moduli being calculated on the basis of an energy approach. In the case of small specimen strains it is assumed that the rods are in a state of tension or compression. The authors use the basic postulates in order to construct a model of the deformation of lightweight isotropic foam plastics with a cellular structure of the rod type. In these plastic foams, the rods may have a nearly constant cross section. The length of the rods is significantly greater than their thickness. The distribution of the rods in different directions is random. 9 refs.

**080022 MICRODYNAMICS OF CRUSHING IN CELLULAR SOLIDS.** Light-weight, open-celled foams and honeycombs can exhibit deformation localization during static crushing as a result of buckling and plastic collapse of cell walls. Localization of deformation is a manifestation of strain-softening behavior that limits transmitted forces through these shock-mitigating materials. Collision tests on two-dimensional cellular solids with strain-softening behavior reveal that with some microstructures, strain-rate effects can stabilize less compliant modes of deformation. When stabilization occurs, it amplifies the intensity of transmitted shocks. (Author abstract)

## Encapsulation

**080023 HEADLINER, DOOR PANEL, SOUND ABSORPTION AND WINDOW ENCAPSULATION - AUTOMATIC TURNKEY PROCESSES.** Injection, inserts, trimming, mold release, part removal, and process control are all integrated together to create a modular, automatic turnkey system to produce both exterior and interior trim parts in production quantities. Three specific interior trim parts are addressed: headliners, door panels, and sound absorption, along with window encapsulation. All of these utilize a multi-step process requiring extensive manual handling, and some require very expensive capital equipment. Currently, not all of the parts are made strictly with polyurethane. But with each part, polyurethane proves to be more conducive to producing a more competitive product by automating the process to full

turnkey system. Different methods of producing polyurethane headliners, door panels, window gasketing, and components for sound absorption are described.

**Extrusion** See Also PLASTICS MACHINERY—Extruders.

**080024 EXTRUSION FOAMING OF THERMOPLASTICS FOR PACKAGING MATERIALS.** The daily task of supplying people with perishable goods, hot food, foodstuffs, fruit, vegetables and transport-sensitive consumer goods requires properly adapted packaging. The choice of packaging materials is, of necessity, made from a stringent viewpoint, to which the properties, the economics and the environmental impact are of decisive importance. Packaging materials made from extrusion-foamed thermoplastics are products that meet these requirements and adapt readily to the variety of needs. (Edited author abstract)

**Flammability** See POLYURETHANES—Foam.

## Flexible

**080025 DYNAMIC COMPRESSION CHARACTERISTICS OF FLEXIBLE FOAMS. I. SIMILARITY MODEL, ANALYSIS, AND EXPERIMENTS.** A simple mathematical model is proposed, based on dimensional similarity parameters, to describe the characteristics of flexible plastic foams under impact conditions. The model assumes that the foam is rate-dependent material, when the dynamic stress is a function of the strain and the strain rate. The similarity parameters include the geometric dimension of the foam, the mass of the absorbing body, and the drop height. By using this model, one can predict the maximum deformation, the maximum decelerations, and the time-pulse period for a wide range of drop heights and masses, by conducting several drop tests. We verified the efficacy of this model by performing free-fall drop tests with flexible polyurethane foam having a uniform density of 240 kg/m<sup>3</sup>. (Author abstract) 3 refs.

Yossifon, S. (NRCN, Beer-Sheva, Isr); Szanto, M. *J Appl Polym Sci* v 34 n 5 Oct 1987 p 2025-2036.

**080026 IMPACT TESTING OF FLEXIBLE POLYURETHANE FOAMS.** Methods of obtaining information on dynamic properties of flexible foams from a limited number of impact tests are considered. The test procedure is based on measuring acceleration and displacement during the entire impact (not only maximum values as required in current standards). Interpretation of the results uses two theoretical approaches: stress-strain relationships and similarity considerations. Each approach has its own advantages. The developed algorithm, applied presently to four commercial packaging foams, allows the plotting of cushioning diagrams and predicts the shape of time-impact dependence for an arbitrary drop height and foam thickness. Properties of composite cushioning structures can be calculated. (Author abstract) 13 refs.

**080027 ENVIRONMENTAL CONSIDERATIONS IN THE PRODUCTION OF FLEXIBLE SLABSTOCK.** Total gas loss by the production of flexible polyether foam may range between 4-20 weight percent, higher densities are mainly blown with carbon dioxide - the lower densities partially with CO<sub>2</sub>, partially with either fluorocarbon and/or methylene chloride. During blow-off approx. 30% of the total gas loss will spontaneously escape from the top surface, the other 70% is contained in the block and will mainly diffuse via the

vertical sides and the bottom of the block. In view of this, trials were conducted in which recycling systems were installed in the plant. The objectives of this newly installed equipment are outlined. Test results show that the system is economically viable.

## Ignition

**080028 INFLUENCE OF FLEXIBLE POLYURETHANE FOAMS ON UPHOLSTERY FABRIC-FOAM MOCK-UPS IGNITIONS BY CIGARETTES.** Fabric and polyurethane foam are major components in most upholstered furniture mock-up systems. Their influence on the system propensity to ignite when exposed to a lit cigarette can be estimated by means of a logistic model. The model, which estimates percent ignition, is uniquely determined by the significant physical properties of the fabric, foam and cigarette employed in the test. The logistic model development rationale along with the selection criteria for the fabrics, foams and cigarettes are presented. Weight and proclivity of the fabric, and air flow of conventional polyurethane foam, were found to be the major physical properties of the mock-up system substrate influencing ignition rates. (Edited author abstract) 13 refs.

**080029 SHOCK MITIGATING FOAMS. 2. STATIC/DYNAMIC CHARACTERISTICS.** Using a selection of both commercially available and laboratory synthesized products, the shock mitigating characteristics of semi-rigid foams are systematically evaluated using both compression tests (static) and swinging pendulum tests (dynamic). It is demonstrated how parameters derived from relatively simple static compression tests may be used to predict the maximum deceleration of an impacting object when striking the foams directly. Following a review of the chemical and physical factors likely to influence energy absorption qualities of foams it is tentatively discussed how such factors may be correlated with the material parameters calculated from the static compression tests. In conclusion, the paper points the way forward to how simple static tests may be used to aid the development of foams with specific shock mitigating properties. (Author abstract) 13 refs.

## Moisture

**080030 DETERMINING THE AMOUNT OF UNFROZEN WATER IN A FOAM PHENOL PLASTIC.** Foam polymers are used as insulators in wall structures, improving the thermal protection considerably while reducing the amount of material required and saving heat in operating buildings; this provides improved thermal comfort, which is particularly important for the harsh conditions in the Far North. The hygroscopicity and the amount of unfrozen water  $W_{uw}$  are major working characteristics of these for use under northern conditions, in addition to the thermophysical and mechanical parameters, a technique for determining water content in a foam phenol plastic is presented. 3 refs.

Efimov, S.S.; Dalbaeva, E.K. *Meas Tech* v 30 n 6 Jun 1987 p 605-607.

## Moisture Control

**080031 THIN FILM PARYLENE COATING OF THREE-PHASE SYNTACTIC FOAMS.** Three-phase syntactic foams composed of silica microballoons poly-

imide binder and voids have good electrical as well as mechanical properties. Consequently, they have been used for encapsulation of electrical devices. However, due to the foam porous structure, moisture may degrade their electrical properties. To reduce moisture absorption by three-phase syntactic foams they have been coated with Parylene C (200 mg·cm<sup>-2</sup>). Moisture absorption by the coated syntactic foam at 95% R.H. at 50°C was determined gravimetrically and found to be 5% wt after 60 days exposure. Diffusion of moisture through the Parylene film was found to follow Fick's law. (Edited author abstract) 21 refs.

## Molding

**080032 TDI MOLDING: OLD TECHNOLOGY, NEW TECHNOLOGY.** The use of TDI in high resilient foam molding was a natural progression from the older hot foam technology. The new HR or 'cold cure' urethane foams were characterized by high resiliency, low hysteresis on compression, and comfort factors approaching those of latex rubber. To make HR foam more compatible with the then current production techniques there was a trend by many foamers to incorporate TDI/polymeric MDI blends in place of the straight toluene diisocyanate. Recently there seems to be a trend back to an all TDI type of formulation. This paper examines the reasons behind the previously increased usage of TDI/polymeric MDI and its advantages. The major part of the paper focuses on why these reasons for changing are either no longer necessary or have been overcome. The current TDI molding technology is presented. 7 refs.

## Morphology

**080033 MORPHOLOGY OF WATER-BLOWN FLEXIBLE POLYURETHANE FOAMS.** A series of four TDI-polypropylene oxide (PO) water-blown flexible polyurethane foams was produced in which the water content was varied from 2 to 5 pph at a constant isocyanate index of 110. A portion of each foam was thermally compression molded into a plaque. The morphology of both the foams and plaques was investigated. A high degree of microphase separation occurs in these foams, and its degree is nearly independent of water (hard segment) content. In the foam with the lowest water content the morphology possesses many similarities to that of typical linear segmented urethane elastomers. Small hard segment domains are present with a correlation distance of about 7.0 nm. When the water content is increased a binodal distribution of hard segment material appears. There are the small hard segment domains typical of segmented urethane elastomers as well as larger 'hard aggregates' greater than 100 nm in size. The larger domains are thought to be aggregates of rich polyurea that develop by precipitation during the foaming reaction. (Edited author abstract) 37 refs.

**080034 OBJECTIVE CHARACTERIZATION OF THE CELL SIZE OF MICROCELLULAR FOAMS.** A technique to characterize the morphology of open- and micro-cellular foams is described. The technique involves measuring the BET surface area of the foam and using a rigorous stereological relationship between the surface area and the average distance between surfaces of the foam. BET surface areas are measured quickly and reproducibly and the stereological relationship enables an exact morphological property to be obtained. The average distance between surfaces can be considered a generalized 'cell size' for many open- and micro-cellular foams. (Author abstract) 11 refs.

**080036 H.R. MOLDED FOAMS BASED ON A MODIFIED POLYETHER POLYOL AND ISOCYANATE BLENDS CONTAINING CRUDE TDI.** Investigations conducted at Dow's R&D Center in Brazil led to the development of Experimental Polyol XB 81230.00, a modified polyether polyol that used in conjunction with isocyanate blends containing crude TDI result in H.R. molded foams with outstanding physical properties. This paper shows the wide range of physical properties that can be achieved through the use of Experimental Polyol XB 81230.00 with different isocyanate blends containing crude TDI. Another purpose of this paper is to introduce our newly developed products, Exp. Polyol XB 81230.02 and Exp. Isocyanate UBX-0018, in response to the local market needs for lower density foams (2.2-2.6 pcf). The physical properties obtained with starting formulations based on these new products are also, herein, compared with those achieved with formulations based on two different copolymer polyols and the widely used 80/20 TDI/MDI blend.

## Reaction Injection Molding

**080039 SIMULATION OF FOAMING IN REACTION INJECTION MOLDING.** Blowing agents are often used in the reaction injection molding process to compensate for the shrinkage that occurs upon polymerization, thereby creating a structural foam part. Controlling the thickness of the solid skin and foamed core is essential to achieve the intended mechanical properties of the molded part. A numerical model was developed to predict the foaming behavior in reaction injection molding. This algorithm employs a novel primitive cell construction to enable it to analyze complex rectangular geometries, including inserts, with a two-dimensional, finite difference solution method. The analysis was applied to foaming of polyurethane in a rectangular cavity. The predicted skin thickness was found to be in good agreement with actual structural foam parts. The results can be used to formulate design guidelines for achieving desired skin/core thicknesses as a function of design, material, and process parameters. (Edited author abstract). 7 Refs.

**080043 NEW AMINE CATALYSTS PROVIDING LESS DISCOLORATION TO PVC COVERED SEMI-RIGID URETHANE FOAM PRODUCTS.** Common catalysts used for the production of semi-rigid foam are triethylenediamine, triethylamine, and dimethylethanolamine, which often cause several odor problems during the manufacturing process, and residual amines in the finished part which cause discoloration of the plastic PVC covering at high temperature. Catalysts which provide less odor during manufacture, less interaction with the PVC covering material, and improved part moldability have been required for the automotive interior application. Toyo Soda has developed two new tertiary amine catalysts, TOYOCAT-HX4W and TOYOCAT-HX35, which are odorless, less effective to PVC and improve flow characteristics for the semi-rigid application. The reactivity associated with TOYOCAT-HX4W is quite similar to triethylamine, however, TOYOCAT-HX35 exhibits stronger blowing tendencies than either -HX4W or triethylamine. (Edited author abstract) 4 refs.

Arai, S. (Toyo Soda Manufacturing Co, Yamaguchi-Ken, Jpn); Tamano, Y.; Tsutsumi, Y.; Lowe, D.W. *J Cell Plast* v 24 n 1 Jan-Feb 1988 p 23-35.

**080044 EFFECT OF WATER ON PHENOLIC FOAM CELL STRUCTURE.** Cell opening in phenolic foam is mainly caused by water in the resin which can produce open cells by two mechanisms. These mechanisms are: (1) phase separation of microdroplets of water that evaporate and leave holes in the cell structure and (2) curing exotherms that raise the temperature of the foaming mixture to a point where water vapor pressure exceeds the cell wall strength and the cells rupture. Lowering the resin water concentration to less than 7% (w/w) and adding both phenol, as a viscosity modifier, and polyglycol, as a heat sink, results in a resin that can be expanded to give a closed cell low K-factor phenolic foam. (Author abstract) 7 refs.

**080045 STUDY OF THE LOW SMOKE POTENTIAL, FLAME RESISTANCE AND PROCESSIBILITY OF HIGH INDEX POLYISOCYANURATE RIGID FOAM.** Recent advances in our isocyanate and catalyst development programmes have stimulated a re-examination of the rigid polyisocyanurate (PIR) foams, and a study has been undertaken to explore the limits of flame resistance, low smoke emission and processibility in these systems. An experimental investigation was therefore carried out to determine the influence of the main PIR formulation parameters on fire and smoke performance of the derived foam. The results demonstrated that low smoke values can be obtained in non fire retarded PIR foams at isocyanate indices of approximately 400. However, to ensure high oxygen index together with low smoke emission, it was found to be necessary to use both high weight fractions of isocyanate (above 0.8) and isocyanate indices above 600. It was demonstrated that the manufacturing difficulties that are traditionally associated with high index PIR formulations can be overcome by the use of a novel catalyst package. Thus a novel class of foam insulation having high isocyanate index and high weight fraction of isocyanate has been identified and given the name SHINDEX foam. (Edited author abstract) 12 refs.

## Marketing

**080050 SPECIALTY RESINS ARE BROADENING DISTRIBUTORS' SUPPLY CAPABILITIES.** Diversification of product lines is a profits-driven trend that is paying off for customer companies in ways that include faster and simpler access to a broader range of resins and compounds. Distributors' inventory buildups are concentrated on performance materials. Coming: more marketing services. (Author abstract)

Toensmeier, Patrick A. *Mod Plast* v 64 n 10 Oct 1987 p 69-71.

## Personnel Training

**080051 ARE YOU SMART ENOUGH FOR THE 21ST CENTURY.** Plastics manufacturing is poised for unprecedented growth in key market areas, as detailed in this special issue. To exploit these opportunities, new materials and processing methods are emerging that some say represent a quantum leap in technological sophistication. Most plastics education programs focus on polymer chemistry, with very little hands-on education in manufacturing. Most machine operators learn their skills on the job. Beginners start by observing experienced operators at work. When trainees first operate a machine, they are supervised closely by more experienced workers. Support for education is tough to justify on the bottom line. Yet, there is no choice. Industry support of plastics engineering and technology programs is precisely what colleges and universities require. They survive through private donations of cash, resins, and equipment.

Process Control See ELASTOMERS—Quality Control.

Quality Control See QUALITY CONTROL.

## Research

**080052 PLASTICS PREPARE FOR TOMORROW'S WORLD.** In the 1930s, phenolic bearings came into use in steel-mill rolling equipment. Their introduction sparked the steel industry to question what other steel parts plastics might displace. Those who examined the question did not foresee just how extensively plastics would compete with steel. In the next century, the position of plastics in the economy will be much more like the position of metals today. Plastics will be roughly on a par with metals in terms of usage, and will likely be a truly mature industry. Even more encouraging is the fact that plastics is not yet a mature technology. We are living in an era in which the tools used by chemists and physicists to probe the molecular world are improving by leaps and bounds. Powerful tools such as computer-aided molecular modeling will shorten the time needed to make significant advances in polymer development.

**PLASTICS LAMINATES** See Also PRINTED CIRCUITS—Manufacture.

**080053 LIGHTER WEIGHT AND LOWER COST WITH FOAM-CORE COMPOSITES.** Foam-core sandwich panels are formed by bonding a face sheet (which may itself be a composite laminate) to a preformed, precut foam slab. Thermoplastic or thermosetting foams are prepared using ordinary foam methods, while syntactic foams are prepared by mixing reinforcing microspheres into liquid resin. The former are recognized for their particularly low cost and light weight, while the latter have remarkably high compressive properties. Their overall cost-performance makes foam-core laminates an excellent answer to many interesting engineering problems. This article discusses material characteristics, reinforcing methods, and other aspects of the subject.

English, Lawrence K. (Materials Engineering, Cleveland, OH, USA). *Mater Eng (Cleveland)* v 4 n 9 Sep 1987 p 51-54.

**080054 NEW, ONE-COMPONENT DICY-FREE EPOXY RESIN SYSTEM DEVELOPED FOR FR-4 GLASS/EPOXY LAMINATES.** This new system does not use dicyandiamide or any other amine as the curing agent and has no problems with crystallization either of the vanish or on the prepreg. The system can be used at a relatively low solvent content and the solvents used have favorable toxicity. Since it is a one-component system it reduces the number of products stored by the laminator and eliminates some blending steps in his manufacturing process. The system produces laminates with an excellent all-round performance in T<sub>g</sub>, moisture resistance, etc. Laminates also exhibit significantly increased resistance to CAF growth, a cause of long-term failure in PCBs. (Author abstract) 4 refs.

Sexton, D. (Dow Chemical Rheinwerk, Rheinmuenster, West Ger). *Circuit World* v 14 n 1 Oct 1987 p 44-46.

**080055 WATER ABSORPTION IN GLASS FIBRE-EPOXIDE RESIN LAMINATES.** Water absorption is a serious problem in all polymeric materials, including the glass fibre-epoxide resin laminates used in printed circuit board manufacture. This paper describes experiments to determine the level of water absorption in these materials under different conditions of relative humidity and temperature using thermogravimetric analysis. (Author abstract) 23 refs.

Smith, C.A. (GEC Research Ltd, Chelmsford, Engl). *Circuit World* v 14 n 3 Mar 1988 p 22-26.

**080056 COMPOSITES IN CONSTRUCTION.** The article describes a 3-layer laminated panel, as a special form of composite actions which is characterized by the use of two thin layers of strong material, denoted as faces, between which a thick layer of light-weight and comparatively weak core is sandwiched. In a structural panel of this type, the faces resist bending moments and in-plane compressive or shear forces. The shear forces normal to the plane of the panel are resisted by the core, which also stabilizes the faces against buckling. This type of construction is efficient structurally due to the large stiffness achieved by spacing apart the most highly stressed elements, namely, the faces.

**080057 SIMPLIFIED ANALYSIS OF TRANSVERSE PLY CRACKING IN CROSS-PLY LAMINATES.** This paper presents a method of analyzing transverse crack initiation and multiplication in symmetric cross-ply laminates. The method is based on the concept of a through-the-thickness inherent flaw and the energy balance principle. With a second-order polynomial assumed for the crack opening displacement, the perturbed stress field due to the presence of ply cracks is determined from the equilibrium conditions. The energy released as a result of ply cracking is then calculated and used to predict the increase in crack density. Based on an experimental correlation of the analytical result, a resistance curve is proposed to be used as measure of the resistance to crack multiplication. The resistance to crack

multiplication is shown to increase with the increasing crack density. (Author abstract) 15 refs.

**080058 THERMALLY INDUCED TWIST IN GRAPHITE-EPOXY TUBES.** This paper discusses an analytical and experimental study to investigate the thermally induced twist in laminated angle-ply graphite-epoxy tubes. Attention is focused on balanced laminates which, contrary to intuition, exhibit twist when the temperature is changed. The twisting is due to the fact that in tube a lamina with a  $+\phi$  orientation and a lamina with a  $-\phi$  orientation must be at slightly different radial positions. The lamina with the greater radial position determines the sense of the twist. Classical lamination theory does not predict this phenomenon and so a more sophisticated theory must be employed. This paper outlines such a theory, which is based on a generalized plane deformation elasticity analysis, and presents experimental data to confirm the predictions of the theory. A brief description of the experimental apparatus and procedure used to measure twist is presented. (Author abstract)

## Degradation

**080059 EFFECT OF HYGROTHERMAL HISTORIES ON MATRIX CRACKING IN FIBER REINFORCED LAMINATES.** Environmental factors that affect matrix cracking in composite laminates include temperature, moisture content, and hygrothermal history. Matrix cracking in laminates exposed to aircraft environments was modeled using a fracture mechanics approach based on strain energy release rates. Residual stress relaxation due to hygrothermal history was found to alter the static mechanical strain necessary to cause matrix cracking in experiments. Depending on material type and hygrothermal history, this effect was shown to either increase or decrease the resistance to matrix cracking. Close agreement between predicted and measured strains at the onset of matrix cracking was obtained using a modification to the fracture mechanics approach. (Edited author abstract)

## Fabrication

**080060 CONTINUOUS LENGTH THERMOPLASTIC COMPOSITE LAMINATES.** Polyphenylene sulfide (PPS) is a thermoplastic engineering polymer with excellent thermal, chemical and electrical properties. Consequently, its use in advanced composites in many applications has been reported in recent years. As a part of our effort to use continuous fiber reinforced composite material based on PPS, authors have developed a proprietary process to form continuous length composite laminates. Laminates having fiber orientation of zero degrees as well as off-axis orientation have been produced. Continuous laminates containing various fabric forms have likewise been made. Mechanical properties of the continuous laminates are listed and compared to properties obtained on compression molded PPS laminates and typical thermoset laminates. Advantages of the continuous laminates compared to thermoset laminates are

increased toughness, reduced moisture uptake and ease of processing. One particular advantage is that due to the thermoplastic nature of these composites, subsequent application of heat and pressure permits reforming all or part of the structure if desired. This reshaping or post-forming procedure cannot be accomplished with thermo-set structures. (Author abstract) 8 refs.

**080063 MODELLING STIFFNESS LOSS IN QUASI-ISOTROPIC LAMINATES DUE TO MICROSTRUCTURAL DAMAGE.** Continuous-fiber laminated composites are known to undergo substantial load-induced damage in the form of matrix cracking, interior delamination, fiber fracture, etc. These damage modes produce significant losses in component performance measures such as stiffness, residual strength, and life. The authors have previously constructed a general model for predicting the response of laminated composites with damage. This paper utilizes the model to predict stiffness loss as a function of damage in quasi-isotropic and angle-ply laminates with matrix cracks. It is shown that the model is capable of predicting the stiffness loss for any layup by utilizing the same input data, thus producing a model which is independent of stacking sequence. The favorable comparisons of the model to experimental results reported in this paper support the validity of the model. (Edited author abstract)

**080064 DELAMINATION BUCKLING AND GROWTH IN A CLAMPED CIRCULAR PLATE.** This paper presents an elastic postbuckling analysis of a delaminated circular plate under axisymmetric compression along its clamped boundary. Von Karman's equations are assumed to govern the deformation of the delaminated layer, while the deflection of the main body of the plate is described by the linear equations of the classical plate theory. Solution of the boundary-value problem is reduced to repeated numerical integration of two initial-value problems. Certain features of the post-buckling behavior are found to be qualitatively similar to the buckling of an axially loaded beam plate containing a one-dimensional delamination. An analytical expression

for the energy-release rate is obtained in terms of the postbuckling solution. The stability of delamination growth under a fixed boundary displacement is examined. The results are compared with previous results for thin-film circular delamination. (Edited author abstract). 9 Refs.

## Filament Winding

**080065 MOEGELICHKEITEN DER PROZESS-SIMULATION BEIM FASERWICKELN.** [Possibilities of Process Simulation in Filament Winding. A Step Toward Economical Component Development.]. This paper presents a concept for the process simulation of filament winding which enables the modeling, winding and production of complex components to be simulated on a computer. Advantages as against conventional procedures lie in the considerable time and material savings obtained; for the winding of nonrotationally symmetrical cores, in particular, good agreement between the winding pattern and the simulation is achieved. A concept for the optimization of machine control parameters for existing winding processes is also planned, with the objective of shortening cycle times. A further desirable feature of this is the ability to estimate flexibility requirements for the winding machine at an early stage of component development and fix them at the necessary level. (Edited author abstract). 9 Refs. In German.

## Fracture

**080067 INFLUENCE OF CYCLIC LOAD AMPLITUDE ON DAMAGE ACCUMULATION AND FRACTURE OF COMPOSITE LAMINATES.** It has become a common practice in the design and certification of composite laminate components to assume that long-term in-service response can be implied from short-term test results. The variable in this extrapolation of behavior is often the cyclic or quasi-static applied load level. These variations in load level can be the source of changes in the damage accumulation and fracture modes associated with the corresponding response. The present paper brings together results from a series of investigations of several composite laminate and material system types in an effort to identify some of the fundamental differences in the damage accumulation and fracture associated with cyclic loading of continuous fiber reinforced composite laminates at high and low cyclic load amplitudes. ## Materials

**080069 COMING SOON: THE IDEAL LAMINATE.** Although today printed wiring board (PWB) laminate materials do an adequate job in most applications, improved laminate materials are still needed to meet the demands of high-performance applications cost effectively. New developments indicate that the ideal laminate of woven and nonwoven Kevlar aramid fiber may soon be available to meet the demands for increased dimensional stability and improved control of the coefficient of thermal expansion (CTE). Nonwoven reinforcements eliminates microcracking and weave print-through that can occur with woven reinforcements. And, new cyanate ester resin families with high glass transition temperatures and low dielectric constants look promising. 4 refs.

**080070 EFFECT OF TESTING METHODS ON THE SHEAR STRENGTH DISTRIBUTION IN LAMINATED COMPOSITES.** An experimental investigation was performed to study the effect of testing methods on the in situ shear strength distribution in fiber-reinforced laminated composites. T300/976 Graphite/Epoxy cross-ply laminates were used in the tests, and rail shear, Iosipescu, and short beam shear fixtures were selected for measuring the shear strengths. The results strongly indicate that the interlaminar shear strength measured from the short beam shear test has no correlation with the inplane shear strengths measured by the other two methods. The rail shear and Iosipescu fixtures provide, in general, consistent results in the measurement of the inplane shear strength. However, the consistency between the results of the two test methods strongly depends on the ply orientation of the test specimens. As shown in the paper, the resultant differences in inplane shear strengths measured from the two test methods could be as much as 50%. (Edited author abstract) 10 refs.

**080071 EINFLUSS DER LAMINATKOMPONENTEN VON CFK-WERKSTOFFEN AUF DAS STATISCHE UND DAS DYNAMISCHE VERHALTEN.** [Effect of the Laminate Components of Carbon-Fiber-Reinforced Plastics on their Static and Dynamic Behaviors]. The static and dynamic properties of a conventional and a modified, toughened matrix system reinforced with two types of high-strength carbon fibers with different fracture elongations were investigated. Three different laminates were chosen, a unidirectional

laminate, a cross-ply laminate and a nearly quasi-isotropic laminate. It is shown that the damage development under both static dynamic loading is delayed when using a toughened matrix system. This delay in damage development results in improved mechanical properties. However, when using a toughened matrix system together with fibers with a high fracture elongation, an improvement in the static properties does not lead to an improvement of equal extent in the dynamic properties. (Edited author abstract) In German. 17 refs.

Baron, Ch.; Schulte, K. *Z Werkstofftech* v 18 n 9 Sep 1987 p 306-313.

**080072 QUERRISSBILDUNG IN 0/90/0 CFK-LAMINATEN.** [Cross-Ply Cracking in 0/90/0 Carbon-Fiber-Reinforced Laminates]. Cross-ply cracking in carbon-fiber-reinforced plastics with thermoset as well as thermoplastic matrix systems was investigated on 0/90/0 laminates with varying 90° ply thickness. Since in an angle ply laminate the 90° ply fails first, the higher strength of the other plies cannot be taken advantage of. For this reason, efforts have to be made to increase the transverse strength (strain) of fiber-reinforced plastics. In the first place, it is therefore necessary to investigate the influence of the various parameters which contribute to the transverse strength. In this work, the influence of the matrix (fracture strain), the fiber matrix interface, voids and the constraining effect of neighboring plies is investigated. With the aid of two-parameter Weibull distributions of the 90° ply fracture strain, which describe the phenomenon of multiple cracking in a specimen, it was found that the constraining effect due to neighboring plies, improved fiber/matrix adhesion and matrix ductility increase the transverse fracture strain, while voids decrease it. (Edited author abstract) In German. 16 refs.

Peters, P.W.M. *Z Werkstofftech* v 18 n 9 Sep 1987 p 313-322.

**080073 RESIDUAL FLEXURAL STRENGTH OF FRP COMPOSITE SPECIMENS SUBJECTED TO TRANSVERSE IMPACT LOADING.** Specimens made of fiber reinforced polymeric composite laminates were subjected to transverse impact loading. The brittle laminate was made of graphite/epoxy (0/90)<sub>2s</sub> and the ductile one was glass/epoxy (+45/-45)<sub>2s</sub>. An instrumented drop weight impact tester was used to load the specimens in the transverse direction with different energy and momentum levels. The residual properties were measured after the impact. It was found that properties changed drastically for the brittle material, while for the ductile material properties changes were more gradual. Damage was controlled by the impact energy level. Specimens with light or nonvisible damage almost maintain their static strength. Impact velocity has a negligible effect on the impact resistance of the material. (Edited author abstract) 16 refs.

**080074 NONLINEAR ELASTIC PROPERTIES OF ORGANIC MATRIX COMPOSITES AT ELEVATED TEMPERATURES.** A model is presented for describing the nonlinear, elastic behavior of unidirectional organic matrix composites at elevated temperatures. The model describes the longitudinal and transverse tensile, longitudinal and transverse compressive, and shear stress-strain relationships, as well as the Poisson ratios. Tests were performed in the temperature range 75 to 350°F using unidirectional laminates made of Fibrerite T300/976 graphite epoxy tape. The constants required in the model for this material were deduced from the data. (Author abstract)

Ha, Sung Kyu (Stanford Univ, Stanford, CA, USA); Springer, George S. *J Eng Mater Technol Trans ASME* v 110 n 2 Apr 1988 p 124-127.

**080075 TEMPERATURE-DEPENDENT DYNAMIC MECHANICAL PROPERTIES OF POLYMERIC LAMINATED BEAMS.** Polymeric composite laminates are being increasingly employed to fabricate

parts which must be designed to operate successfully in dynamic mechanical environments under various temperatures. In order to develop a set of experimental data for evaluating the predictive capabilities of new computer-aided design tools for predicting the elastodynamic response of engineering structural components operating under different temperature regimes, an experimental program was undertaken to study the elastodynamic response of E-glass/Epon cantilever specimens and AS-4 graphite/Epon cantilever specimens subjected to discrete ambient temperatures in the range of -10°F to 300°F at a constant relative humidity of 75 percent. Design charts demonstrating the variation of damping and the dynamic longitudinal elastic modulus were then plotted as a function of temperature for these specimens. (Edited author abstract)

## Processing

**080076 PROCESSING SCIENCE OF THICK-SECTION COMPOSITES.** A comprehensive process model was applied successfully to the cure of thick-section laminates. The cure of these laminates provided very critical tests of the process model because of the demand for in-process control of a highly exothermic cure reaction and the problem of managing generally poor and non-isotropic thermal conductivities in the processing unit. The process model involves all aspects of chemical reactor theory; reaction kinetics, chemoviscosity, thermochemical parameters, heat and mass transfer, and fluid dynamics. It was demonstrated that the temperature-time and pressure-time cycles could be computed and an autoclave-vacuum bag process operated in accordance with these computed process conditions in real-time. (Author abstract) 7 refs.

## Technology Transfer

**080078 INDUSTRY GROWTH TIED TO TECHNOLOGY, DESIGN INNOVATIONS.** U.S. consumption of every type of lamin te, for all applications, will likely increase by 50 percent or more within the next 10 years. Total laminate usage will reach 10 billion square feet in 1995. About 6.7 billion square feet of low and high pressure laminates were used in panel products manufactured in 1986. During the five-year period from 1982 to 1986, the use of low pressure overlays increased 137 percent as total consumption of vinyl films, light-weight papers, impregnated foils/papers, thermo-fused laminates and hot stamped foils rose from 1.28 to 3.03 billion square feet. Although popularity for solids and patterns is equally split, especially in the kitchen countertop market, the trend is going away from wood grains in favor of textured

styles. The majority of laminates in the home are basic solids and other patterns. Wood grain laminates are still being used in furniture and commercial case goods, but even that is swinging to solids. It is less popular because most designers are becoming purists, and if they want that look, they go for the real thing.

## Thermal Effects

**080080 THERMO-VISCOELASTIC RESPONSE OF GRAPHITE/EPOXY COMPOSITES.** The thermoviscoelastic behavior of composite materials is studied analytically using a special finite-element formulation. Numerical results on stress and deformation histories are obtained for both unnotched and notched graphite/epoxy composites subjected to mechanical and thermal spectrum loads. The results indicate that time-dependent effects are important in composites with matrix-dominated layup orientations. Such effects also strongly depend on the specific environment condition and load spectrum applied. (Edited author abstract)

## Vibrations

**080081 NONLINEAR VIBRATION OF LAMINATED COMPOSITE PLATES IN HYGROTHERMAL ENVIRONMENTS.** This paper addresses the phenomena of nonlinear vibration of moderately thick laminated composite plates in hygrothermal environments. The shear-deformable plate theory is modified to account for midplane stretching due to large deflections, large rotations, and dimensional and constitutive changes due to moisture-induced swelling effects and temperature-induced expansions and contractions. The in-plane hygrothermal dimensional changes are accounted for by introducing fictitious forces and moments, and the hygrothermal dimensional changes along the thickness of the plate are explicitly incorporated in the assumed form of the deformation field. The free vibration of a cantilevered laminated composite beam in hygrothermal environments is discussed as an illustrative example to demonstrate the applicability of the proposed methodology. (Edited author abstract)

**080088 FOR 40-PLUS INJECTION MACHINE BUILDERS, IT'S 'BACK TO BASICS'.** The shift in emphasis from automation to advancements in primary machine engineering reflects what many injection machine manufacturers view as a plateau in control technology. Further control advancement awaits the arrival of artificial intelligence capabilities, or standardization of machine communication protocols. Representative of this possible new stage in electronic maturation is the current affordability, processing power, and programming flexibility of microprocessor-based controllers, now standard on virtually all machines. Moreover, injection molders in diverse industries report that the sluggish implementation of CIM technology in injection molding stems from efforts to optimize machine performance first. This has become especially important to satisfy the demands of just-in-time manufacturing for rapid production of zero-defect parts.

Wilder, Robert V. *Mod Plast* v 65 n 1 Jan 1988 p 44-48.

**080089 FULLY AUTOMATIC PART DEMOULDING AND STORAGE ON INJECTION MOULDING MACHINES.** Various sized production units had to be built for the automation of a complete injection molding shop. The clamping forces of the machines ranged from 1250 to 16,000 kN. On each line a robot demolds the articles from the machine and deposits them in compartments in transport cages. These stand on a conveying system, which also serves as buffer station next to the injection molding machine. The driverless transport system (DTS) takes the full cages away and delivers empty ones to the machine. An additional conveyor belt enables any possible rejects to be sorted out by the handling equipment. Moldings requiring finishing can be picked up from the conveyor belt and deposited in a transport cage after finishing.

**080093 FEEDING, METERING, PROPORTIONING COME UNDER TIGHTER CONTROL.** More consistent product quality, faster startup, and improved efficiency are the primary driving forces behind a growing trend to tap computer capabilities in extrusion, compounding, blow molding, injection molding, and other processes. In addition to improved accuracy, microprocessor-based equipment provides the ability to closely monitor materials consumption and to detect problems before they cause downtime. Processors are increasingly custom blending compounds with diverse formulations of virgin pellets, powders, and additives. Computerized control permits precision metering of costly additives, as well as quick startups because of the ability to program and store recipes. Accurate control of ingredients and the ability to record exact levels of material processed are paying off in coextrusion operations, including sheet products and blow molded containers with multiple layers.

Wilder, Robert V. *Mod Plast* v 64 n 11 Nov 1987 p 61-63.

**080094 WHAT'S SPECIAL ABOUT LARGE MACHINES FOR BODY PANELS?** The requirements on a body-panel molding machine are predicated by the materials and parts they are to mold. For one thing, the specialized engineering thermoplastics for body panels demand more critical molding conditions than other resins. Those conditions are made all the more critical by the nature of the parts - large-area, thin-section (and growing thinner all the time), often complexly shaped, and with critical surface appearance and dimensional tolerances. The machinery has to be capable of providing good shot-to-shot repeatability with little scrap. For these reasons, machines serving this market commonly have specialized screws, state-of-the-art controls, and fast-acting hydraulics. Hydraulics and controls need to be tightly coupled, providing varying rates of injection pressure and speed to fill the mold properly.

Fallon, Michael R. (Plastics Technology, New York, NY, USA). *Plast Technol* v 34 n 4 Apr 1988 p 68-71, 73, 75.

**080095 DEVELOPMENTS IN QUALITY IN PLASTICS MANUFACTURE.** Feedback to functions such as Design and Production Control is important to ensure improved manufacturing reliability. With the advent of automated handling and the incorporation of in-line measurement a way has been opened for the exploitation of direct statistical machine control. Advantages include the ability to anticipate out-of-control situations and to apply corrective action before defective products are produced. In tracing the development of machine control towards this goal several stages can be identified. Discrete

controllers were originally used to control processing variables within certain limits; this was followed by the use of tooling control systems involving measurements of variables such as pressures and temperatures of material; practical control systems based on direct component measurement require some form of automated handling of the product. A variety of machines is now available which incorporate the capability of handling and some form of measurement for each component. 6 Refs.

## Costs

**080096 INJECTION MOLDING: TRYING TO LIVE UP TO EXPECTATION.** The cost of large-tonnage machinery is causing those with a stake in the market to seek alternatives. Du Pont Co.'s Automotive Products Dept., is experimenting with software that enables it to convert large injection machines for an injection-compression process. Some machinery suppliers are developing innovative alternatives to standard machines with higher productivity at a relatively lower cost in mind. Husky Injection Molding Systems, is developing its Tandem System which uses a third central platen to enable two standard molds to be installed in the machine. It also features a hot-runner system and packing cylinder in the third platen, a means to independently clamp the molds, and a robot for automated parts removal from either mold station. Stubbe GmbH, has developed a twin-station injection molding machine especially for the production of automotive exterior parts. The Giga machinery line is said to double production capacity at less than half the energy requirement.

Fallon, Michael R. *Plast Technol* v 34 n 10 Sep 1988 6p.

## Design

**080097 REFINEMENTS IN TECHNOLOGY SHARPEN COMPETITIVE EDGE.** Quality and efficiency are being improved by better machine designs, a greater use of microprocessors, particularly as control centers, and overall increased automation. Newer software packages are not only multiplying functions but are also monitoring production refinements. The equipment is becoming more user-friendly.

**080101 SMC: DEFENDING CHAMP FOCUSES ON SPEED, CONSISTENCY.** The most dramatic advance in SMC technology has been the introduction of high-speed, short-stroke presses with advanced parallelism and velocity controls that have enabled molders to achieve uniform part thickness within at least 0.005 in. Microprocessor controls on these new presses permit programmed closed-loop velocity control during flow and programmed pressure profiling during curing. The industry is focusing on automating the molding process in an ongoing effort to achieve sub-60-sec part-to-part cycle times. Molders are also working to automate and more carefully monitor the bonding cycle. Several molders have installed, or are preparing to install, sophisticated materials-handling equipment and robotics, including automated charge cutting and weighing units, charge compacting and preheating systems, automatic press loaders and unloaders, robotic deflashing, and fully automated bonding systems, as well as quick-change systems for tooling.

## Electric Drive

**080102 ALL-ELECTRIC 'CLEAN MACHINES' FIND A HIGH-TECH NICHE.** Injection machines of this type, which are powered entirely by electric servo motors rather than hydraulics, are finding a solid niche in tight-tolerance molding applications, especially those where strict requirements on cleanliness favor an oil-free molding environment. The machines have won quick acceptance from molders of small, tight-tolerance medical, electronic, and optical parts, especially those requiring 'clean-room' conditions. A key advantage of the all-electrics is that they reportedly are more precise than most hydraulic machines. This is attributed to the high accuracy of the ac servo motors and to the elimination of such variables as oil viscosity, oil breakdown, and oil compressibility.

**080104 CAVITY TRANSFER MIXER: A BLENDER FOR ALL SEASONINGS.** The Cavity Transfer Mixer (CTM) invented by Dr. G.M. Gale at Rapra Technology Limited, is described as a highly efficient add-on blending device for extruders. The basic theory and development work are described to illustrate the power law relationship which the device achieves in mixing compared with others

achieving only linear relationships. Practical applications are described illustrating the very wide range of uses. These include: achievement of a constant temperature behind the die to give consistent profile, completion mixing using masterbatch, improved electrical properties, reduction of nerve, improved output and direct injection of ingredients. The article concludes with a description of most recent modifications including separately driven CTMs to give maximum mixing efficiency. (Author abstract) 16 refs.

Hindmarch, Ron S. (Rapra Technology Ltd, Shrewsbury, Engl). *Mater Des* v 8 n 6 Nov-Dec 1987 p 331-339.

**080105 NEW COMPOUNDING EXTRUSION OPTIONS.** Inline reduced-bore discharge permits continued use of efficient high-speed twin-screw compounders without as much power consumption or polymer-temperature rise as associated with full-bore discharge. The temperature rise has been lowered by a factor of 2.5. And axial thrust can be reduced by 60 percent, increasing the service life of bearings, gears, and other drive components. Another option, the generation of pressure for melt extrusion by centrifugal force, presents the opportunity for isothermal pelletizing and lower power consumption.

**080106 FUNDAMENTALS OF THE RESIDENCE TIME BEHAVIOUR IN EXTRUDERS.** Residence time behavior, mixing conditions and flow behavior in an extruder influence the product and the product quality. Basic principles of mixing processes for distribution purposes are described. (Edited author abstract) 18 refs.

Schuele, H.; Meder, S.; Mueller, C. *Kunstst Ger Plast* v 77 n 12 Dec 1987 p 32-34.

**080107 PRESSURE BUILDUP IN THE FEED ZONE OF A SINGLE SCREW EXTRUDER - THE EFFECT OF DENSITY COMPRESSIBILITY.** The effect of density compressibility of granular polymerized solids on the pressure development inside the feed zone of a single screw extruder was calculated. Results indicate that, for a given flow rate, density compressibility enhances pressure rise inside the extruder, remedying the underestimation of previous theory. A substantial rise in pressure buildup may result for compressibility above a certain level. This may explain observed surging during the processing of low bulk density materials. (Author abstract) 5 refs.

Sun, Tzu-Hsiung (Nat'l Ping-Tong Agriculture Inst, Ping-Tong, Taiwan). *Adv Polym Technol* v 8 n 1 1988 p 11-15.

**080108 MODELING OF CONTINUOUS MIXERS. PART I: THE COROTATING TWIN-SCREW EXTRUDER.** A simple model is developed for the hot melt closely intermeshing corotating twin-screw extruder. With this model, and more specifically with its extension to the complete nonisothermal, non-Newtonian situation, it is possible to understand the extrusion process and to calculate the energy, specific energy, and temperature rise during the process with respect not only to viscosity of the melt, but also to the screw geometry (location and number of transport elements, kneading sections and blisters, pitch, positive or negative, screw clearance, and flight width) and screw speed. To support the theoretical analysis, model experiments with a Plexiglas-walled twin-screw extruder were performed, in addition to practical experiments with melts on small-and large-scale extruders, with very reasonable results. (Edited author abstract) 46 refs.

Meijer, H.E.M. (Eindhoven Univ of Technology, Eindhoven, Neth); Elemans, P.H.M. *Polym Eng Sci* v 28 n 5 Mid-Mar 1988 p 275-290.

**080109 PERFORMANCE STUDY OF BARRIER SCREWS IN THE TRANSITION.** This paper defines through a mathematical model the advantages and disad-

vantages of barrier screws as far as their melting and mixing performances in the transition zone are concerned. The melting analysis is based on the Tadmor's original model, and the flow in the melt channel is considered to be non-Newtonian and nonisothermal. The performance of these barrier screws is investigated for the solids channel in terms of melting rate/interfacial contact area; melting efficiency; melting length; solid bed velocity profile; and power consumption in the melt film at barrel surface. For the melt channel, their performance is investigated in terms of pressure buildup; average bulk temperature; power consumption in the melt channel and in the main flight clearance at barrel surface; and average bulk mixing. (Edited author abstract) 14 refs.

Amellal, K. (Algerian Inst of Petroleum, Boumerdes, Algeria); Elbirli, B. *Polym Eng Sci* v 28 n 5 Mid-Mar 1988 p 311-320.

**080110 EXPERIENCE IN USING EXTRUDERS WITH GROOVED FEED ZONES.** Extruders with grooved bushes and appropriately designed screw feeds are now the state of the art in high performance extrusion technology. Modifications to the geometry of the bush/screw system or changes in operating conditions need to be carefully tested, as they can bring not only advantages but also disadvantages. Grooved extruders can make an appreciable contribution to economy of production in extrusion processes. In the 20 years or so since the introduction of this process technology it has undergone considerable further development. This has enabled manufacturers to process particular materials, and to make plastics components or finished products with desired properties, to an extent which would not have been possible without grooved extruders. In English and German.

Kraemer, A. *Kunstst Ger Plast* v 78 n 1 Jan 1988 p 3-6.

**080111 DETERMINING THE RESIDENCE TIME BEHAVIOUR IN EXTRUDERS.** Three methods of determining the residence time in plastics extruders are discussed. Some of the topics discussed are inductive measurements; the effects of screw speed and die inlet pressure. Other topics covered include extruder screw geometry; the twin screw performance; incineration of plastics; and plastics density determination. In English and German.

Schuele, H.; Meder, S.; Mueller, C. *Kunstst Ger Plast* v 78 n 1 Jan 1988 p 26-28.

**080112 MELT FLOW IN SCREW CHANNELS.** Finite element analysis (FEM) can be used to calculate and solve problems of fluid mechanics or heat transfer. In this paper, the FEM method is applied to the calculation of flow in screw channels of single screw extruders. The model on which the simulation is based, however, only describes flow processes in completely filled channels; solids transport and phase transition remain unconsidered. Hence this solution is applicable only for the description of transport processes in melt fed extruders and in the metering section of single-screw extruders with multi-zone screws. The advantage of FEM over approximation equations commonly used today is that both the geometry of the screw channel (front flight face angle, flight base radiusing) and material properties can be precisely described. It is not therefore necessary to start from the assumption of a rectangular screw channel and power law behaviour of the melt.

Menges, G.; Limper, A.; Schwenzer, C. *Kunstst Ger Plast* v 78 n 2 Feb 1988 p 34-36.

**080113 'KTX' TWIN-SCREW EXTRUDER.** The 'KTX' series twin-screw extruders were especially developed to satisfy customers' diverse and unique requirements for plastics compounding, complicated process conversions from batch to continuous systems, and simplification of plastics compounding plants. The barrel employs a 'building-block' system and the screw a segment system. The twin-screw is driven by a high-torque high-power drive unit employing a planetary gear reducer mechanism and a multi-tandem thrust bearing. This paper

describes the basic design principles of the KTX, the concepts of kneading and mixing, and applications of the equipment. (Author abstract) In Japanese.

**080118 LEAKAGE FLOW OF AN ISOTHERMAL POWER LAW FLUID.** A numerical technique has been developed to accurately determine the leakage flow of a power law fluid in a screw extruder. The effect of the leakage flow on total throughput becomes rather large for small values of the power law index. The contribution of the pressure flow to the leakage flow is considerable, particularly when the flight clearance is large and the power law index small. The velocity profiles in the channel and clearance are strongly affected by the pressure gradient, flight clearance, and power law index. The power consumption in the flight clearance has a large effect on the overall power consumption and energy efficiency, especially for large values of the power law index. 8 Refs.

Rauwendael, Chris (Raychem Corp, Menlo Park, CA, USA); Housz, J.F. Ingen. *Adv Polym Technol* v 8 n 3 Fall 1988 p 289-316.

**080119 ANALYSIS OF THE PERFORMANCE OF COOLING EXTRUDERS IN THERMOPLASTIC FOAM EXTRUSION.** The performance of cooling extruders widely used in thermoplastic foam extrusion was analyzed, by numerically solving the equations of motion and heat transfer. For the analysis, a power-law model was used as the constitutive rheological equation, describing the viscosities of a mixture of a fluorocarbon blowing agent and a low-density polyethylene melt (or polystyrene melt). The parameters in the rheological model were determined using the data of C.D. Han and C.Y. Ma. In obtaining numerical solutions of the equations of motion, an integration method was employed to overcome the problem of numerical instabilities. This study provides a rational basis for the design of cooling extruders widely used in thermoplastic foam extrusion and for the selection of optimum extrusion conditions in producing thermoplastic foams. (Edited author abstract). 18 refs.

## Granulators

**080120 CALCULATION OF THE POWER REQUIRED TO DRIVE ROD-PROCESSING GRANULATORS.** For purposes of the study the total power required to drive the granulator,  $N_g$ , was taken to consist of three components, i.e., the power consumed when not producing anything, viz., the power consumed when idling; the power consumed in extruding the polymer rods and passing them to the cutter, and the power consumed in cutting the rods into granules. With a view to obtaining data for calculating the idling power, granulators in two standard sizes were tested. As a result of processing the experimental results it was ascertained that the idling power can be expressed in terms of the dimensions of the main working part of the granulator, viz., the cutter and its rate of rotation. The power consumed in extruding the polymer rods and passing them to the cutter depends on the kind of material being processed, the design of the extraction system, the degree of pressure exerted by the tensioning drum, and several other factors. The force required to extrude a polymer rod depends on the physical and mechanical properties of the material to be processed, the diameter of the opening in the die, the exit velocity of the melt, and the required diameter of the granules. By using the authors expressions the power required to drive rod-processing granulators can be calculated at the design stage.

Takhtuev, B.G. *Chem Pet Eng* v 22 n 5-6 May-Jun 1986 p 186-187.

**080121 GRANULATORS ARE COMING INTO THE MAINSTREAM - AT AFFORDABLE PRICES.** Typical of the microprocessor controls in use on granulators is the Allen-Bradley SLC 150 programmable controller, which can monitor 19 sensors and transmit 22 signals. Cumberland's microprocessor control package uses thermocouples to monitor heat in the cutting chamber, bed knives, bearings, and evacuation bin. These sensors signal temperatures that could cause granulate meltdown, which can clog the machine and take it out of service. One of the more sophisticated examples of controls linked to a remote computer is the Operatorless System. It comprises a conveyor and parts separator, and an auger granulator with two throat sizes - 8 by 10 in. and 10 by 12 in. Among the controls Polymer Systems offers are two that signal backup in the cutting chamber: a zero-speed switch and an ammeter.

Hydraulic See Also PLASTICS—Transfer Molding.

**080122 SEALING AND GUIDE SYSTEMS FOR INJECTION MOLDING MACHINES.** It is important that the moving platens on injection molding machines are guided accurately and move without jerking at all speeds. This can be achieved by using modified polytetrafluoroethylene (PTFE) for the sealing- and fabric reinforced

composites for the guide system. The sealing and guide systems described for hydraulic cylinders on clamping units have proved themselves in practical operation. Due to the materials excellent surface slip characteristics and high resistance to abrasion, they achieve service lives many times the service lives of conventional seals. Even after several years in operations, no wear could be found on dismantled piston seals and guides.

Roesler, H. *IPE Int Ind Prod Eng* v 12 n 1 Jan 1988 p 18-19, 22.

## Materials

**080123 USE OF ECONOMICALLY ALLOYED AND NICKEL-FREE STEELS IN POLYMER-PRODUCTION EQUIPMENT.** Inspections of the corrosion state of active equipment and tests of metallic structural materials were conducted at plants involved with the production of low-pressure polyethylene (LPPE), polypropylene (PP), polyvinyl butyryl (PVB), and propylene oxide combined with styrene (POS). The investigations that we conducted indicated that in the production of LPPE the polymerizing reaction vessels can be fabricated from steels 07Kh13AG20, 08Kh18GN2T and 08Kh22N6T without detriment to the reliability and longevity of the production equipment. In the production of PP, series-produced equipment in the zone where the catalytic agent is prepared can be built from steel 08Kh22N6T. In the production of PVB, the nickel-free steel 07Kh13AG20 and the double-layer steel with the 08Kh13 cladding layer can be used in the polymerization stage. In the production of POS, steel 08Kh21N6M2T is recommended for basic equipment. 2 refs.

**080125 FASTER DESIGN AND FABRICATION OF PRESS-MOLDS: THE 'EXPRESS-MOLD'.** The new universal modular units developed by the special planning, design, and production-engineering bureau for relay apparatus of the Kiev Production Combine for Relays and Automation Devices for Automatic Thermosetting-Plastics Machines offer several advantages as compared with the familiar widely employed units. The system now contains four blocks, which may be used to produce up to 70% of the plastic parts. Standardized designs of mold inserts have been developed for each block. A fast design system (FDS) has been developed for all types of mold inserts. This has reduced the volume of design effort by a factor of 2-3. Operation of such press molds at the Kiev Production Combine for Relays and Automation Devices has demonstrated their convenience in operation: rapid readjustment, a lighter installation (as against 120-9 kg), less space occupied in storage, more convenience in transportation.

Diner, I.G. *Sov Electr Eng* v 58 n 2 1987 p 108-109.

**080126 DAS HELPS MAINTAIN PRECISION OF INJECTION MOLDING MACHINE.** A data acquisition system is being used by Bell Communications Research Inc. to monitor the critical process parameters of a closed-loop injection molding machine; the machine is used in the study of ultra-high precision injection molding. The process parameters incorporated so far as the screw and clamp position (or velocity), the mold temperature, and the melt temperature. The system is self-contained and portable. The equipment in the system consists of a Compaq 286 transportable computer running ASYST software, a DT-2801 A/D card, and Omega Omni-Amp battery-operated type J thermocouple amplifiers. These and other aspects of the system are discussed.

**080133 L-FORM INJECTION MOULDING MACHINE.** In L-form injection moulding machines, the injection unit is perpendicular to the clamping unit. L-machines consist of well tried and tested modules of an injection moulding machine series with microprocessor control. They are outstanding because of their increased economy. By comparison with comparable injection moulding machines of standard design and the same clamping force, they produce 90% more moulding for only 30 to 40% more procurement cost. Some of the topics discussed include machine lay-out, and two practical examples of mouldings produced on L-form injection moulding machines.

Sonntag, R. *Kunstst Ger Plast* v 78 n 2 Feb 1988 p 9-10.

**080134 MOULD CHANGING SYSTEMS FOR INJECTION MOULDING MACHINES.** This report is intended to describe the current state of the development and employment of mold changing systems. A survey both of machine manufacturers was made. These companies were: AEG, Kassel; Battenfeld Automatisierungsgesellschaft, Meinerzhagen; Ludwig Engel KG, Schwertberg/Austria; Fischer Werke, Tumlingen; Kloeckner Ferromatik Desma GmbH, Werk Maintal; Mannesmann Demag Kunststofftechnik, Schwaig; Maschinenfabrik Netstal, Naefels/Switzerland; Ninkaplast, Bad Salzufen; Preh, Bad Neustadt, as well as further unnamed injection molding firms and machine manufacturers. The article discusses the components of mold changing systems and some criteria for choosing suitable automation concepts. (Edited author abstract) 4 refs.

Benfer, W. *IPE Int Ind Prod Eng* v 12 n 1 Jan 1988 p 32, 34-39.

**080135 RECENT TRENDS IN PLASTIC MACHINERY.** Kobe Steel, Ltd. manufactures various type of plastics pelletizing and molding machinery such as continuous mixers, extruders, and injection and compression molding machines. Recent progress and improvements to these plastics machines are introduced. Requirements for the pelletizing equipment are to increase capacity, reduce energy consumption, and improve product quality. Large-sized injection and compression molding machines which can be controlled precisely shall be developed for users such as the automotive industry. (Author abstract) 4 refs. In Japanese.

Inoue, Kimio. *R&D Res Dev Kobe Steel Ltd* v 38 n 2 Apr 1988 p 3-5.

**080136 KONZEPTE FUER COEXTRUSIONS-BLASFORMANLAGEN.** [Design Aspects of Co-extrusion Blow Moulding Machines]. As a result of the increasingly high diffusion resistance requirements for packaging containers, co-extrusion blow moulding is gaining in importance. After discussing the barrier materials and adhesion promoters used in this process, the author describes the different types of melt distributor and examines various design aspects of co-extrusion blow moulding machines. (Author abstract) 6 refs. In German and English.

**080138 INJECTION MOULDING SURVEY: GETTING THE MACHINE TO SUIT THE WORK.** Manufacturers of injection moulding machines now customize machines to suit individual production requirements. The largest injection machine built so far is an ES3200 with 32000kN clamping force; it will be used to mould refuse containers. A second large machine, coded ES 50000/2000, with two injection units, is producing the heaviest pressure pipe fittings in the world, in polypropylene and HDPE, with shot weights of up to 40Kg. A new programme of multi-color/multi-component machines, running parallel with the NCIII series is based on the typical modular concept. The concept allows for many combinations: horizontal/vertical, parallel/horizontal, horizontal L, or piggyback. All variations can be delivered with or without a rotary table for the mould.

Anon. *Plast Rubber Int* v 13 n 2 Apr 1988 5p.

**080139 DIE FORMFUELLUNG IM VORAUS BE-RECHNEN.** [Injection Capacity of Injection Moulding Machines]. On the basis of the EUROMAP 4 recommendation, it has been possible to develop a measuring process which reliably relates the rate of injection with the melt pressure during the mould filling process of an injection moulding machine, also in the case of machines equipped with servo valves mounted directly on the injection cylinder. Particular reference is made to the necessity to correct inaccuracies of measurement caused by the pressure loss in hydraulic return lines from the injection cylinder. Test readings are utilised for the evaluation of several practical designs of hydraulic systems. (Edited author abstract). In German.

Johansen, Ole; Frederiksen, Lars S. *Plastverarbeiter* v 39 n 5 May 1988 p 122-129.

**080140 PROBLEMLÖSER IN JEDEM FALL?.** [Rapid Mould Changing Systems]. The problem of reducing set-up times in the injection moulding shop cannot be solved by rapid mould changing systems alone. Set-up times can be optimised by proper planning and systematic procedures. Large investments are not necessary. It would be desirable if a limited number of rapid changing systems could be agreed upon and these were in conformity with a specific standard and could be supplied with every make of machine. The initiative, however, must come from the injection moulders themselves. (Author abstract). 5 refs. In German.

Heuel, O. *Plastverarbeiter* v 39 n 5 May 1988 p 130-140.

**080141 NICHT NUR, UM ZEIT ZU SPAREN.** [Automatic Mould Changeover]. Automatic mould changeover on injection moulding machines has been viewed primarily from the time-saving angle to date. The greater comfort and, in particular, safety of the fitter have been of secondary importance. It is precisely the safety factor, however, that should not be forgotten, since the danger of injury whilst undoing the screws is considerable. The chief common features of semi-automatic and fully automatic mould changeover are secure mould clamping, no open-circuit operation of the hydraulic hoses, no mixing up of the heating/cooling lines and no danger of injury. Although the preference is still for the semi-automatic system at present, fully automatic mould changeover will become increasingly established in the wake of the VDMA standardisation committee's work and the associated reduction in costs. (Edited author abstract). In German.

Anon. *Plastverarbeiter* v 39 n 5 May 1988 p 148-149.

**080142 COST-CUTTING ANCILLARY EQUIPMENT-A REVIEW.** Two fundamental factors to consider in evaluating ancillary equipment are: cycle time and part quality. Five areas to look for in such equipment include: mold handling in/around the machine; mold locating in the machine; mold clamping; utility connections; material/color changes. A new range of 'low-tech' mold clamps has been introduced by TEK Machinery Ltd, covering 10-20mm size and with prices starting at just £8.00. Manufactured in hardened steel they are supplied complete with adjustable 12mm hexagonal fixing bolt and jacking screw.

Anon. *Plast Rubber Int* v 13 n 3 Jun 1988 4p.

**080143 HOT COMPETITION AMONG BUILDERS; BETTER DAYS FOR BLOW MOLDERS.** With 30 or so machinery makers vying for U.S. business, and with markets aching to be opened, blow molding equipment of every kind is undergoing transformation that is resulting in increased performance capabilities (some of them startling), faster cycles, and greater reliability. In all types of blow molding equipment, the trend is toward more advanced control systems and more automation. To make better use of advanced controls, builders are engineering in such refinements as smoother operating proportional hydraulic systems for mold clamping, clamp systems that handle heavier molds, increased sophistication in multilayer systems, and techniques for molding complex shapes with a minimum of scrap.

Smoluk, George R. *Mod Plast* v 65 n 8 Aug 1988 p 50-52, 54, 56.

**080144 BLOW MOLDING CONTROLS BEGIN TO MAKE CIM A MORE LIKELY PROSPECT.** An important factor fueling the drive for increased controls sophistication is growing interest in applying plantwide networking, statistical process control (SPC) automation, and flexible manufacturing cells to blow molding. A fundamental baseline for such advanced concepts is a system that can track machine performance, adjust for process variations, report QC parameters to a central computer, and perform other computer-integrated manufacturing functions. The drive to manage more blow molding process variables from a single interactive control unit is gaining momentum for a number of reasons. One is growing interest by blow molders in computer-integrated manufacturing techniques, which are drastically simplified by plugging into a single control unit that tracks more of the CIM-relevant functions of machines. Networking of blow molding plants is technologically at an early stage, but it can have a dramatic effect on bottom-line production performance.

Sneller, Joseph A. *Mod Plast* v 65 n 8 Aug 1988 p 57, 60, 62.

**080145 FUER SCHWERE WERKZEUGE UND HOCHWERTIGE FORMTEILE.** [Large Injection Molding Machines for Heavy Molds and High-Grade Moldings]. Krauss-Maffei Kunststofftechnik GmbH (Munich) offers a new series of injection molding machines. These M-series machines cover the clamping force range from 10,000 kN to 36,000 kN. Eight clamping units and seven injection units of the same design principle are available as modules. The characteristic features of these large-scale machines are short cycle times, short setting up times, user-friendliness, energy-saving, low-noise and suitability for the heaviest of molds. In the new type of clamping system the clamping force is introduced into the moving platen via four pressure columns. This design solution also leaves enough space between the platen for a wide range of ejector systems. The clamping cylinder is also of a new design. The clamping force is built up via a tandem cylinder, whereby two work surfaces arranged in series permit a considerably reduced cylinder diameter. (Edited author abstract). In German.

**080146 ANALOGIEN ZWISCHEN DUROPLAST -**

**UND ELASTOMERMASCHINEN.** [Injection Molding Machines for Crosslinking Molding Compounds: Analogies Between Thermoset and Elastomer Machines]. The injection molding process now occupies an established place in the production of thermoset and elastomer molded parts. It has considerable advantages compared with the traditional compression molding and transfer molding processes, particularly when it comes to the scope for automation. The process sequence and hence machine and mold engineering are very similar for thermosets and elastomers. A non-crosslinked molding compound must be plasticized and metered 'cold' without the crosslinking reaction commencing. Following this, the molding compound is injected into a heated mold in which the crosslinking or vulcanization reaction proper takes place. The moldings can then be demolded while still hot. A more detailed observation of the individual functional units of an injection molding machine will reveal certain differences between elastomer and thermoset machines. The essential criteria to be borne in mind when selecting a machine are explained in this report. (Edited author abstract). 1 Ref. In German.

## Pumps

**080148 GEAR-PUMPS IN EXTRUSION.** This paper covers the design of gear pumps and their applications in plastics extrusion. Some of the topics discussed are the mechanical assembly, pump delivery rate, extrusion system optimization criteria, and energy conservation of gear pumps. In English and German.

Bolder, G.; Langhorst, H. *Kunstst Ger Plast* v 78 n 1 Jan 1988 p 6-10.

Repair See PLASTICS—Extrusion.

Scheduling See PLASTICS PLANTS—Personnel.

## Temperature Control

**080149 CHILLERS GEAR UP FAST FOR THE INTEGRATION CONNECTION.** Advantage Engineering is a major source of mold temperature controllers (water and oil) and chillers (portable and central). The Intellitemp microprocessor temperature controller is an intelligent programmable controller that incorporates dual digital displays, programmable alarms and self-diagnostics. Any of three microprocessor control types are available on Advantage's portable chillers: simple solid state, Checkmate anticipating diagnostic controller, and Precision controller. Conair's contributions to the automation connection include mold temperature controllers and chillers with optional computer-compatibility. Among them are Thermolator mold temperature controllers. A computer-compatible microprocessor-based control, Compumate 3400, is a new addition to Mokon's temperature controllers. Sterling, Inc. reports that the basic operator-set unit remains the backbone of its mold temperature controller line.

Smoluk, George R. *Mod Plast* v 64 n 11 Nov 1987 p 74-76.

## Tools, Jigs and Fixtures

**080150 ATTACHING HEAVY MOLDS TO LARGE INJECTION MACHINES.** Mammoth machines and molds for automotive body panels require special procedures for secure mold mounting. DuPont has established internal standards and procedures to ensure satisfactory clamping/support of molds. The procedures include: mold acceptance; pre-mold installation; mold transportation; mold clamping; jack block support; overhead support; mold installation; mold removal.

Coleman, R.C. (DuPont Co); Masters, S.G. *Plast Technol* v 34 n 4 Apr 1988 p 78-81.

## Wear

**080151 DAMAGE OF THE WORKING ORGANS OF EXTRUDERS IN THE PROCESSING OF PLASTICS.** In order to gain actual data on the distribution of wear along the working organs, to establish the zones of maximum damage, and to determine the kind of wear in the different zones, the authors investigated the extruders in several plants. The investigations included checking of the diameters of the worm turns and depressions in every working zone; the width of the turns at the crest and at the base was measured with a micrometer, and the internal diameter of the bushings with dial inside calipers. It is found that the most efficient way of hardening of the working organs is the application of thick coatings by means of different welding or atomization processes; in comparison with nitriding, it provides a multiple increase in wear resistance. The main advantage of such coatings is their relative thickness (2-3 mm) and uniformity of mechanical properties (hardness, strength) across the layer; this allows us to exploit fully the wear tolerances during exploitation. The use of wear-resistant parts in extruders has improved their reliability and increased the unit capacity and productivity. 4 refs.

**080152 WEAR TESTS OF PLASTIC PROCESSING MACHINES BY MEANS OF KRYPTON-85-METHOD.** Since 1979 the Tisza Chemical Works and the Institute of Isotopes of the Hungarian Academy of Sciences have carried out wear tests by means of radioisotopes in order to find the wear characteristics and the expectable endurance of plastic processing tools and extruders. Authors briefly introduce the krypton-85-method for wear tests and the experiences gained by this method. In this research work the wear-rates of different kind of tools were compared as a function of the material processed. In the tests two type of plastic were processed: plastics without any ingredients (i.e. natur) and plastics containing different ingredients (i.e. composites). (Author abstract)

**080153 CHANCE UND HERAUSFORDERUNG FUER DIE KLEINEN. [Flexible Production].** Automation, rationalisation and material flow planning are vital factors, particularly when it comes to small and medium-sized plastics processing companies. The reason for this is that specialist suppliers are being increasingly tied into the purchasing and materials management schedules of the large companies. The trend towards the division of labour in production is prompting the large companies to increasingly delegate their own production out-of-house. Much of the responsibility is passed to the supplier company as well. The prerequisite here is controlled quality on the basis of guaranteed standards. Over and above this, minimum response times are also required, even for special-purpose designs. Finally, growing impor-

tance is coming to be attached to a precisely defined rastered depositing and stacking of components and assemblies, since customer companies are making increased use of robots in further processing. (Author abstract). In German.

Bauer, Reinhard. *Plastverarbeiter* v 39 n 5 May 1988 p 162-166.

**080154 SCHRITT FUR SCHRITT ZU MEHR QUALITAT. [Automation of Manufacture: Step by Step to More Quality].** Small and medium-sized manufacturing companies are finding themselves under increasing pressure to be more flexible. This applies particularly to series producers who work on the basis of time numbers, as in the injection molding sector, where customers are calling for increasingly small batch sizes within increasingly short deadlines on the basis of the 'just-in-time' principle. Competition is forcing companies to implement thorough rationalization measures, i.e. to improve their entire organizational and production engineering infrastructure by means of computer-aided automation systems. This report describes how a computer system for capturing and processing production data brought about a marked improvement in the quality and flexibility of production in an injection molding company after only a short time. (Author abstract). In German.

**Computer Aided Manufacturing** See Also PLASTICS INDUSTRY—Computer Aided Manufacturing.

**080155 COMPUTER SIMULATION SYNERGIZES DESIGN, MOLD BUILDING, PROCESSING.** The message coming clear to more processors is that computer-aided design, engineering and manufacturing takes the costly and time-consuming trial-and-error out of designing components and molds. The shorter lead times that result also provide the mobility needed to meet competitive challenges. (Author abstract)

Wilder, Robert V. *Mod Plast* v 64 n 10 Oct 1987 p 52-54, 56.

**080156 INTRODUCTION OF UP-TO-DATE CAD/CAM TOOL PRODUCTION AT VSZM.** In the present 5-year plan-period the development of the tool production is one of the objectives of the company. The company wishes to reach her objectives of shortening the tool production period, the increasing of the quality and durability as well as the objective of increasing the productivity by the introduction of CAD/CAM system and by the starting up of further up-to-date high-performance CNC machines. The method which is established at VSZM is formulated in such a way that the introduction of CAD/CAM is to be realized with the least possible complications and losses. It is based on the existing limited hardware, and with the extensions of the users softwares and their development and practical use it trains the personnel for the application of CAD/CAM. 3 refs.

## Fume Control

**080161 CLEAN UP YOUR ACT WITH FUME INCINERATION SYSTEMS.** There are basically four types of fume incineration systems, all of which incorporate thermal oxidizers that destroy VOC's by high-temperature conversion of hydrocarbon-laden fumes to harmless water vapor and carbon dioxide. While all the various types of systems have acceptable cleanup efficiencies, each system is different in theory of oxidation and cost of operation; each has its own benefits and drawbacks. The purpose of this article is to illustrate the differences between incineration systems, and to provide examples of current installations. The four types of systems are: common afterburner; catalytic converter; recuperative thermal oxidizer; and the regenerative thermal oxidizer. Each is described from the equipment, cost, and performance points of view.

**Management** See PHONOGRAPH RECORDS.

## Personnel

**080162 TECHNICAL NOTE: OPTIMAL MAN-POWER ASSIGNMENT TO INJECTION MOLDING MACHINES.** The Corporate Operations Research group and Plant Industrial Engineering department decided to develop a computer system that would group machines and assign them to operators in order to minimize the total operators required to attend all injection molding machines. Among the requirements of

the computer system were: the system must be executable on the plant computer hardware; the system should allow quick response to handle unexpected changes; the system should have the flexibility to vary the maximum travel distance among machines assigned to an operator, and the maximum number of machines that can be assigned to an operator; and the system should allow the user to assign operators.

Chen, Jack (American Airlines, Dallas, TX, USA); Saxena, Umesh. *Ind Manage (Norcross GA)* v 29 n 6 Nov-Dec 1987 p 31-33.

**Quality Control** See Also PLASTICS—Extrusion; PLASTICS MACHINERY—Control.

**080163 ON-LINE QUALITY CONTROL FOR IMPROVED COMPOUNDING.** Technological aspects of most compounding operations have now reached generally accepted, if not optimal, levels of precision. For this reason, research aimed at improving product quality and lowering production costs now centers on quality-control methods. The primary function of quality control in a compounding operation is the integration of pertinent process data with a feedback control system. Effective quality control reduces start-ups and shutdowns and therefore helps minimize creation of waste and non-standard material. This result is especially important to those who process a variety of plastic materials.

Dreiblatt, Adam (Werner & Pfleiderer Corp, Ramsey, NJ, USA); Herrmann, Heinz; Nettlinbreker, Hans-Jurgen. *Plast Eng* v 43 n 10 Oct 1987 p 31-34.

**080164 JUST-IN-TIME IN THE PLASTICS PROCESSING INDUSTRY.** This paper reviews the applicability of just-in-time concepts to the plastics processing industry focusing on three specific areas: quality management, technological requirements, and raw material purchasing practices. Plastics processing is inherently batch oriented, due to the time required to stabilize the molding process. Just-in-time is generally thought to apply to repetitive rather than batch processes. The authors found that a number of just-in-time concepts are quite applicable to plastics processing. (Author abstract) 15 refs.

Richmond, Lee E. (Conwed Plastics, Minneapolis, MN, USA); Blackstone, John H. Jr. *Int J Prod Res* v 26 n 1 Jan 1988 p 27-34.

**080165 GELPERMEATIONSCHROMATOGRAPHIE IN DER QUALITAETSICHERUNG.** [Gel Permeation Chromatography in Quality Control]. Gel permeation chromatography provides quantitative information on average molecular mass and molecular mass distribution; in plastics processing it can be used to monitor the quality of both the starting material and the finished articles. Taking PA, PC, and PES as examples, it is shown how gel permeation chromatography can be used to measure thermal degradation caused during processing, and the effects of incorporating reinforcing agents or adding reclaimed material. (Author abstract) 6 refs. In German and English.

## Robot Applications

**080166 WHAT'S AHEAD IN ROBOTS.** Robots for molded parts removal and other plastics applications, while still used by a minority of plastics processors, no longer carry an exotic 'high-tech' aura, but are gradually taking their place among other types of auxiliary equipment. Vendors are easing maintenance by reducing the number of parts, integrating controls with those of primary processing machines, and making robots faster with more powerful microprocessors.

Fallon, Michael (Plastics Technology, New York, NY, USA). *Plast Technol* v 33 n 11 Oct 1987 p 71-75.

**080167 PROCESSORS TAKE A SECOND, HARDER LOOK AT ROBOTS.** The learning curve for

robots is rising as processors deploy these tools to boost quality and productivity and not to trim labor costs. Reports from diverse processors show that a few such companies now find robots to be an effective weapon in the battle to retain and increase their share of the expanding worldwide market for plastics goods. Far from serving as a type of electromechanical labor substitute that works for lower pay, robots can provide: reduced reliance on disappearing low-cost unskilled labor; improved product quality with more consistent processing and handling of components; increased productivity through repeatability, accuracy, accelerated production, and integration with downstream operations; and the flexibility to meet changing manufacturing requirements.

Wilder, Robert V. *Mod Plast* v 64 n 8 Aug 1987 p 48-51.

**PLASTICS PRODUCTS** See Also PACKAGING MATERIALS—Plastics; POLYMERS—Industrial Applications.

**080168 LARGE PLASTIC PARTS ARE MAKING IT BIG.** The long-term goal of plastics to replace metals in diverse large-part markets is now more in sight than ever. Process-oriented material refinements and a widening range of processing choices are increasingly making designing with plastics the logical approach for reliable, attractive, and cost-efficient large parts. This is illustrated in this paper by a number of examples. (Edited author abstract)

## Assembly

**080170 ULTRASONICS & MICROPROCESSORS TEAM-UP FOR EFFICIENT ASSEMBLY.** Ultrasonic assembly is a fast, clean and efficient method for assembling or processing rigid thermoplastic parts or films and synthetic fabrics. Various ultrasonic assembly techniques are used by all segments of industry to join plastic to plastic and plastic to metal parts or other nonplastic materials thereby replacing or precluding the use of solvents, adhesives, mechanical fasteners, or other consumable items. The article discusses how recent advances in controls for ultrasonic processes have greatly improved their capabilities, versatility and precision. Subjects covered include how ultrasonic assembly works, processes, joint design, equipment, and others.

Barmmer, Bonnie (Branson Ultrasonics Corp). *Assem Eng* v 30 n 11 Nov 1987 p 40-44.

**080171 FLEXIBLE AUTOMATION OF ASSEMBLY.** International competition has forced companies to work towards maintaining their positions to a far greater extent than ever before. The competition is essentially marked by the necessity of adapting to changing market needs, frequently linked to small batch size and uncertainty regarding the number of items required. From the

production angle, this means flexibility in production and flexibility in assembly. (Edited author abstract) In German and English.

Muno, H. *Kunstst Ger Plast* v 77 n 9 Sep 1987 p 12.

**Coatings** See POLYURETHANES—Molding.

**Computer Aided Design** See Also PLASTICS PLANTS—Computer Aided Manufacturing.

**080172 ANWENDUNG VON CAD/CAE BEIM AUSLEGEN EINES FORMTEILS AUS POLYACETAL.** [Application of CAD/CAE in Designing a Polyacetal Model Part]. Along with the penetration of plastics into areas which so far have been reserved to other materials, especially metals, the amount of work connected with the design and development is increasing. As an example of technical calculations involving the use of a computer, the stresses and deformations occurring in a molded part, namely a fastener clip for the automobile industry, are determined. (Edited author abstract) In German. 2 refs.

Hess, J.; Eiden, G. *F&M Feinwerktech Messtech* v 95 n 6 Sep-Oct 1987 p CA122-CA124.

**080173 USE OF CAE IN THE DESIGN OF PLASTICS COMPONENTS.** This paper covers the application of computer aided engineering in the design of plastics components. Some of the topics discussed include: computer aided design; cost reduction; reduced product development time; and improved product quality. Other topics covered are: data generation and interpretation; processing of geometrical data; data records handling; finite element method network as well as rheological, thermal and mechanical design.

Schmidt, J. *Kunstst Ger Plast* v 78 n 2 Feb 1988 p 3-8.

**080174 COMPUTER-AIDED MOLD AND DIE DESIGN.** The properties of plastics parts depend not only on the particular resin used, but also to a great extent on how it is processed. Accordingly, the flow properties of the thermoplastics to be employed must already be considered when designing the molds and dies and setting the processing conditions. The rheological behavior of plastic melts is strongly dependent on the processing conditions encountered. For the past several years, computer programs with which the flow phenomena in molds and dies can be simulated have been increasingly developed and put into practice. For these reasons, the design of new tooling should always be accompanied by computer-aided analysis. Utilizing known or assumed processing data and given tool geometry along with material data, suitable programs can be used to design or optimize molds or determine better processing parameters from the results of the calculation.

## Computer Integrated Manufacturing

**080175 MICROPROCESSOR-CONTROLLED INJECTION MOULDING MACHINES - MODULES FOR BUILDING CIM SYSTEMS.** The realization of CIM (computer-integrated manufacturing) in injection molding operations places new demands on the machines: these are explained in terms of three basic features of automated production. One essential feature can be inferred from the term itself: integrated manufacturing requires all areas related to production to be connected together in the interests of problem-free exchange of information. A second characteristic of current CIM activity is step-by-step introduction of systems, by means of which individual areas of an operation are covered one after the other. The third aspect is the obvious fact that each CIM system must be designed quite individually for the circumstances of a specific operation. 7 refs.

## Failure

**080176 ASPECTE METODOLOGICE IN DETERMINAREA DURATEI DE VIATA IN FUNCTIONARE A MATERIALELOR PLASTICE.** [Methodological Aspects in the Determination of Service Life of Plastic Materials]. The paper estimates the level of knowledge in the field of service life evaluation in order to make a correlation among: 1) the nature and the intensity of the stresses; 2) the assessment of the properties; 3) the failure criterion (f.c.). For polymers presenting the yielding point on the tensile curve, the following f.c.s. are being advanced based on the analysis of the experimental data: a) the loss of the deformation capacity in the oriented state; b) the appearance of the brittle fracture replacing the ductile one. The choice of one f.c. or another is to be done according to practical, operational requirements. (Author abstract). 14 Refs. In Romanian.

**Injection Molding** See Also PLASTICS MACHINERY—Molding Machines.

**080177 INJECTION MOULDING TOOL FOR BRUSH HANDLE PRODUCTION.** The molding to be produced is the handle of a ceiling brush, designed to meet technical and practical specifications. A nuckel signed thread has been chosen for screwing the handle into the wooden body of the brush, a hook on one side allows it to be suspended in a bucket when required and two holes on either side take a piece of string by which the brush can be hung up. The surface of the handle is grooved longitudinally and crossways in order to prevent the hand from slipping during use. Polyamide is used as molding material for the handle.

**080178 CALIBRATION OF HIGH PRESSURE POLYURETHANE METERING UNITS WITH A COMPUTER CONTROLLED CLOSED LOOP CALIBRATION UNIT.** Production of quality polyurethane parts using high pressure impingement mixheads require reactants to be delivered to the mixhead at precisely controlled temperature, pressure and flow rates. Manual calibration of metering system flows and temperatures have been a time consuming procedure which leads to wasted chemicals, and chemical disposal expenses. Also, the accuracy of manual calibration is dependent upon the skill and care of the calibrating technician. There are basically two approaches to reducing chemical wastes, potential for worker exposure and technical errors: flow meters and closed loop weighing systems. This paper describes a 'State of the Art' weight based closed loop calibration system and compare its operation to manual calibration and flow meters.

**080179 STAMPED METAL PARTS FOR EMBEDDING IN PLASTIC ARTICLES.** Rounded metal parts for embedding in plastics, e.g. threaded inserts, have been extensively described. Such parts are simple and cheap to make, and they can be incorporated either in an injection moulding process, by injecting the plastic around them, or by retro-fitting into mouldings, e.g. by ultrasonic techniques. In contrast to such parts as these, this article deals with parts which are flat or only slightly shaped, and are made by die-stamping of sheet metal or strip steel, then anchored into plastic mouldings. In all cases the metal parts are attached to the plastic in such a way that they cannot be pulled out.

**080180 ORIENTATION TECHNOLOGY AND COMMERCIAL PRODUCTS FROM A UNIQUE ROLL ORIENTATION PROCESS.** Orientation can produce, at a minimum, an order of magnitude improvement in physical properties of low cost plastic resins. A unique, large-scale, commercial rolling mill process for continuous orientation of plastic sheet has been developed. A number of oriented materials have been commercially produced by this rolling mill process with a wide variety of physical properties attained. This has resulted in large volume sales of many interesting commercial products. Over the last thirty years, numerous researchers have conducted studies to evaluate the theoretical aspects of the rolling process, and the resultant properties. Most commercial oriented products are of relatively small cross sectional size such as fibers and film. The process reported herein produces heavy cross section oriented sheet. A new class of high strength thermoplastic materials is now available for design engineers to use. Long-term strength properties are often 10 to 100 times better than with unoriented thermoplastics. (Edited author abstract).

**080181 IMPACT PROPERTIES OF MOLDINGS OF RIGID POLYURETHANE MADE BY RIM.** Impact properties of moldings made by Reaction Injection Molding (RIM), which are integral-skin foams and have sandwich structures consisting of high density skin and low density core layers, were investigated by Charpy impact tests. A remarkable difference in failure mode was observed depending upon the layer composition. The failure modes were classified as: tensile fracture-type, and buckling fracture-type. The Charpy impact value of the buckling fracture-type became over two times greater than that of the tensile fracture-type. In addition, the layer composition at which the fracture mode changes from the tensile fracture to the buckling fracture was predicted by using the static flexural properties of the moldings at comparatively low temperatures and the reciprocity law of time-temperature. ## Planning

**080183 PLANIRANJE RAZVOJA I LANSIRANJE PROIZVODA PRERADE POLIMERA NA TRZISTE.** [Processes of Planning, Development, and Marketing of Polymer Products]. The paper deals with the phases of product planning, development and marketing. The author emphasizes the need for coordination of marketing, production and technical functions of development in polymer processing. The present state of organization of polymer product development is assessed and improvements are proposed for future work. (Edited author abstract) In Serbo-Croatian. 6 refs.

Opsenica, Dane (INA-OKI, Zagreb, Yugosl). *Polimeri (Zagreb)* v 8 n 10-11 Oct-Nov 1987 p 312-314.

## Processing

**080184 MORE FOR YOUR MONEY FROM FAST-CYCLING POLYMERS.** One of the most important and complex design decisions involved in many application-development programs is determining how to get the most parts out the door and to the consumer. Reliability, consistency, and quality simply cannot be at the expense of productivity. This article discusses how processibility can be optimized without undue sacrifice in performance. Subjects covered include polymer performance characteristics, processing considerations, molding, and others.

English, Lawrence K. (Materials Engineering, Cleveland, OH, USA). *Mater Eng (Cleveland)* v 104 n 11 Nov 1987 p 35-38.

## Quality Assurance

**080185 EXPERT ESTIMATION IN THE PRODUCTION OF PLASTIC ITEMS.** The paper is devoted to the question of organizing an expert commission. Methods of selecting the experts by using a triple test, confirmation of their competency, and consistency in the results of processing the expert estimates of three kinds are discussed: pairwise comparisons, ranking, and number estimates. Moreover, the informational iterative procedure during which the expert can refine his ranking by becoming acquainted with arguments of colleagues on the defects noted, is investigated. 6 refs.

## Recycling

**080186 COMMINATION AND WASHING OF PLASTICS: NEW DEVELOPMENTS IN PROCESSING TECHNOLOGY.** Many plastics processors (e.g. manufacturers of bottle crates, PETP bottles or agricultural films) are being forced to an increasing extent to seek out ways for utilizing their used products. At the same time, the quality requirements for the sorted plastics reprocessed in the processing factory have increased. Fast, highly automated processing plants make the highest demands on the raw materials used, as regards their purity and uniform quality. The essential modules of the waste reprocessing plant are precommminutors, cutting mills, fine grinding mills, and washers. Further developments of these are described.

Beyer, S.; Herbold, K. *Kunstst Ger Plast* v 77 n 8 Aug 1987 p 3-5.

## Surfaces

**080187 STRUCTURE OF SKIN LAYER IN INJECTION-MOLDED POLYPROPYLENE.** The structure of skin layer in injection-molded polypropylene which displayed a clear two-phase structure of skin and core has been studied by means of wide-angle x-ray diffraction, small-angle x-ray scattering, melting behavior, density, dynamic viscoelasticity, and tensile test. In general, a polypropylene melt crystallizes under a high shear stress in injection molding. From these facts, it was concluded that the skin layer is composed of so-called 'shish-kebab'-like main skeleton structures, whose axis is parallel to MD, piled epitaxially with a -axis-oriented imperfect lamellar substructure. (Edited author abstract) 20 refs.

## Viscoelasticity

**080188 VISCOELASTIC-PLASTICS BOTTLE CRATES.** The purpose of the study is to analyze the viscoelastic-plastic behavior of bottle crates under creep load. In so doing, various components of the deformation (plastic, elastic and viscoelastic) are ascertained and described mathematically. The computation was performed on beer crates with a base area of  $425 \times 285$  mm and a height of 260 mm, but can be applied to any other type of bottle crate. 5 refs.

**Visibility** See TRAFFIC SIGNS, SIGNALS AND MARKINGS—Plastics Applications.

## Waste Disposal

**080189 ARE SHIPBOARD PLASTICS ALL WASHED UP.** The long-life characteristics which favored use of plastics in the marine (and other) environments are now threatening its growth and even its current usage levels, particularly as an at-sea packaging material. Close to a billion pounds of plastic are discarded into the world's waters every year; the world's merchant fleet disposes of approximately 639,000 plastic container annually; and U.S. Navy vessel's discharge four tons of plastic daily. Shippers and fishermen have begun modest voluntary efforts to rid the ocean of plastics waste. The problem of recycling of plastic products used at sea, and especially that of plastic fishing nets, 25 million pounds of which are lost or discarded at sea is considered.

**080191 ESTABLISHING THE CRITERIA FOR SELECTING SUITABLE INTERLAYER MATERIAL FOR DOUBLE-LAYERED FILAMENT-WOUND CFRP STRUCTURES.** Choice of inter-layer material

for a double-layered carbon-phenolic/ carbon-epoxy filament wound structure has been investigated. Differential thermal contraction during cooling after the final stage of curing cycle has been determined by laminate theory. Practical problems in achieving exact matching of fiber-content in two layers have been discussed and consequences of such mismatch have been demonstrated theoretically. Typical thermal expansion behavior of three different inter-layer materials (viz. a phenolic resin, a laminating grade epoxy resin and a low molecular weight adhesive grade epoxy resin) have been studied by thermo-mechanical analysis. The criteria for selecting suitable inter-layer material for the two-layered structure have been suggested. (Author abstract) 11 Refs.

**080193 SURVEY OF CURRENT STATUS AND FUTURE TRENDS IN REINFORCED PLASTICS COMPOSITES.** The production of reinforced plastics has constantly increased since the Second World War. With a forecast growth rate of 8 to 12 percent annually over the next decade, composites are one of the fastest growing sectors of the plastics industry. Advanced composites will show the largest expansion, due to a strong increase in demands in aerospace and military markets. Penetration of advanced composites into big-volume markets has not occurred, but it is believed that advances in both materials and machinery will accelerate the mass-production of these materials. High-volume composites will see a less rapid growth rate but demands for these materials will continue to increase. Land transportation will remain the largest and will be also the fastest growing market for high-volume composites. Current status and future trends in the uses of various reinforcing fibers and matrix resins are presented. Hurdles to the expansion of reinforced plastics are also discussed. (Author abstract) 31 refs.

## Additives

**080194 COUPLING AGENTS AND MODIFIERS: TARGETING UPGRADES PERFORMANCE.** Trends in the development of coupling agents and surface modifiers include formulations that are more resin specific, as suppliers target opportunities for their materials in advanced composites and engineering thermoplastics. In many cases new coupling agents and modifiers not only improve the bond between polymer and filler but also upgrade aspects of resin performance beyond such traditional rheological enhancements as greater wetout and higher throughput. Suppliers seeking lucrative market niches via tailored product reformulation create a user bonus in couplers and surface modifiers that establish new and more broadly applicable levels of value.

**Applications** See Also BUILDING MATERIALS—Plastics; METALS AND ALLOYS—Bonding; THERMOPLASTICS—Physical Properties.

**080196 ADVANCED COMPOSITES FOR AIRFRAMES AND CAR BODIES.** Advanced composites are high-performance composites, often capable of replacing metals. Today's advanced composite technology is driven by improved resin matrices and fiber/fabric reinforcements, and advances in equipment/processes. Aero/aircraft and passenger car composite applications have more differences than common denominators. Certain processes can be used in any of these applications, such as filament winding, pultrusion, and variations of mat molding, but there are significant differences in process economics. Low production volumes and high production costs for aero/aircraft applications allow higher fabrication costs compared with passenger car production.

**080198 STATISTISCHE BEURTEILUNG DER DATEN VON SCHWINGFESTIGKEITUNTERSUCHUNGEN AN CFK-VERBUNDSTRUKTUREN.** [Statistical Evaluation of Experimental Results from Fatigue Strength of Carbon Fiber-Reinforced Plastic Composites]. Measurement results concerning the safe life history of cyclically loaded carbon fiber-reinforced plastic composites yield a statistical frequency distribution and a resultant rate of failure. Comparison with appropriate types of distribution allow a proof whether the number of cycles to failure correlates well with fracture probability. This paper investigates the problem of estimation of the

minimum sample size required, yet sufficient for drawing precise conclusion from measured data distributions. Some calculations show that sample sizes do not need to exceed 10 to 12 samples in each test series if constant variance is assured notwithstanding their absolute magnitude. (Edited author abstract) In German. 10 refs.

**080199** SCHÄDIGUNGSMECHANISMEN VON C F K-NIETVERBINDUNGEN. [Damage Mechanisms in Riveted Carbon Fiber-Reinforced Plastics]. The behavior of carbon epoxy composite materials jointed by rivets is studied in order to evaluate the design parameters under different climate conditions. The effect of the variation of the fiber material, fabric, and tape were studied together with different rivet diameters, layer geometry, fiber angles, and laminate thickness. It is shown that riveted joints lose a part of their strength due to local deformation. (Edited author abstract) In German. 9 refs.

Wetzel, Dirk (DFVLR, Braunschweig, West Ger). *Mitt Dtsch Forsch Versuchsanst Luft Raumfahrt* 87-08 1987 p 189-209.

**080200** SCHÄDIGUNGSMECHANISMEN UND ABSCHÄTZUNG DER LEBENSDAUER VON CFK-LAMINATEN. [Damage Mechanisms and Service Life Prediction in Carbon Fiber-reinforced Laminates]. A commonly observed failure mode in laminated composites is the delamination between composite layers. Delaminations may result from interlaminar stresses that develop at the stress-free edges or discontinuities like holes, cut fibers, matrix cracks, or impact damage. Furthermore, delaminations may grow under cyclic loading up to the final damage state where the delaminated sublaminate starts to buckle. This paper describes quantitatively the growth of delaminations in unnotched and notched graphite/epoxy laminates and the final damage state. Test results are presented with analytically predicted results. (Author abstract) In German. 25 refs.

**080201** ANNEALING EFFECTS OF CARBON FIBER-REINFORCED EPOXY RESIN COMPOSITES IRRADIATED BY ELECTRON BEAMS. Carbon cloth-reinforced epoxy resin composites were irradiated with 2 Mev electrons at room temperature and then annealed in air for 2 h at temperatures up to 180°C. A considerable decrease in the three-point bending strength occurred when the irradiated composites were annealed in the temperature range of 115-135°C which is below the glass transition temperature  $T_g$  of the matrix resin, while the bending strength remained unchanged up to 180°C for the unirradiated composites. In the dynamic viscoelastic spectra of the irradiated matrix, a new relaxation appeared at the temperature extending from 50°C to just below the matrix  $T_g$  and disappeared on annealing for 2 h at 135°C. Annealing also decreased the concentration of free radicals existing stably in the irradiated matrix at room temperature. (Edited author abstract). In Japanese. 5 refs.

**080202** INFLUENCE OF FIBRE AND MATRIX FAILURE STRAIN ON STATIC AND FATIGUE PROPERTIES OF CARBON FIBRE-REINFORCED PLASTICS. The potential benefits of the overall strength of carbon fiber-reinforced plastics with conventional matrix systems can only be realized to a relatively small extent in view of the fact that design criteria for CFRP components presently allow, for aerospace use, a maximum strain of about 0.4%. Under static loading conditions first matrix cracks must be expected in the transverse piles above 0.4% strain. Shifting the maximum allowable strain level to higher values would significantly increase the profitability of composites. It is shown in this paper that

increasing the matrix failure strain (ductility) yields a pronounced improvement of the mechanical properties (under static and fatigue loading) and a shift of the crack initiation level to higher strain values. (Edited author abstract) 15 refs.

Baron, Ch. (DFVLR, Cologne, West Ger); Schulte, K.; Harg, H. *Compos Sci Technol* v 29 n 4 1987 p 257-272.

**080203** EFFECT OF STRESS RATIO ON NEAR-THRESHOLD PROPAGATION OF DELAMINATION FATIGUE CRACKS IN UNIDIRECTIONAL CFRP. The effect of the stress ratio on near-threshold growth of delamination fatigue cracks was investigated with unidirectional laminates made from Ciba Geigy 914C prepregs (T300/914) and from Toray P305 prepregs (T300/#2500). Tests of delamination fatigue crack propagation were carried out under mode I opening loading by using double cantilever beam specimens. The normalized gradient of energy release rate was controlled in load-shedding tests. In the region of crack growth rates above about  $5 \times 10^{-10}$  m/cycle, the growth rate was expressed as a power function of fracture mechanics parameters. A controlling fracture mechanics parameter is discussed on the basis of fractographic observation and mechanism consideration. A new phenomenological law of fatigue crack propagation is derived. (Edited author abstract) 17 refs.

**080205** STUDIES ON FRACTURE MECHANISMS OF CFRP BY ACOUSTIC EMISSION METHOD. Carbon fiber reinforced plastics (CFRP), which is one of the advanced composites, have excellent properties of specific strength and rigidity. They have been used for lightening the mass of machines and the structures. It is thought that the fracture mechanisms of composite materials are so complicated that an investigation is necessary to make clear the fracture behaviors and mechanisms of the materials. Therefore, by using the results of frequency analysis of the acoustic emission of the model CFRP in the previous paper, it is found, in this paper, that the acoustic emission which is produced by the deformation and the fracture of unidirectional composite laminates and three directional ones are classified by the frequency, and that the fracture mechanisms of these composite materials can be clarified. (Author abstract) In Japanese. 4 refs.

**080206** NOTCH SENSITIVITY OF MULTIDIRECTIONAL CARBON FIBRE-REINFORCED POLYIMIDES IN FATIGUE LOADING AS A FUNCTION OF STRESS RATIO. Multidirectional laminates of carbon fibre-reinforced bismaleinimide with a central hole as a notch were examined in a fatigue loading test using various stress ratios (R). In the case of  $R = -1$ , an increase in the number of load cycles was found to diminish the notch influence on fatigue strength. At  $R = 0.1$  no complete failure was observed when the maximum

stress was less than or equal to the static tensile strength up to a load cycle range of  $2 \times 10^6$ . Damage observed that would affect mechanical behavior in fatigue loading by a faster decrease of notch sensitivity was more pronounced than in that reported for notched multidirectional carbon fibre-reinforced epoxy resin specimens. (Author abstract) 16 refs.

**080207** FRETTING FATIGUE STUDIES OF CARBON FIBRE/EPOXY RESIN LAMINATES. PART II: EFFECTS OF A FRETTING COMPONENT ON FATIGUE LIFE. The fretting fatigue properties of carbon fiber reinforced plastic (CFRP) laminates with stacking sequence  $[\pm 45, 0, \pm 45, 90, \pm 45]_{2s}$  (Laminate A) and  $[0, 90, 0, 90]_{2s}$  (Laminate B) were examined and compared with similarly executed plain fatigue tests. With three different pressures of fretting pads and pad materials (TAl6V4, Al7475 and a CFRP laminate with mainly 0°-plies) there were 9 experimental fretting variables. Apart from strongly differing behavior of both laminates, it has been shown that there is an important influence of fretting on the number of cycles to fracture. A reduction of the number of fatigue cycles due to fretting up to three orders of magnitude was observed for Laminate B, whereas Laminate A was relatively insensitive to the fretting component. (Author abstract) 6 refs.

Schulte, K. (DFVLR, Cologne, West Ger); Friedrich, K.; Kutter, S. *Compos Sci Technol* v 30 n 3 1987 p 203-219.

**080208** POLY(PIVALOLACTONE) COMPOSITES: AN ULTRA-CRYSTALLINE THERMOPLASTIC COMPOSITE PREPARED BY MONOMER IMPREGNATION. Poly(pivalolactone) (PPL)/carbon fiber prepreps were prepared by in-situ anionic polymerization. Excellent wetout is achieved at high fiber loadings. The mechanical properties of laminates are compared with PEEK and PPS based materials. The exceptionally high crystallinity (approximately 75%) of PPL endows it with good temperature and solvent resistance despite its low  $T_g$  (approximately 10°C). Composites exhibit excellent fracture toughness and can be processed at a relatively low temperature (250°C) for a crystalline thermoplastic. However, the low  $T_g$  of PPL may limit the usefulness of this material as a composite resin. (Author abstract) 16 refs.

**080210** EFFECT OF SELECTIVE ADHESIVE INTERLEAVING ON INTERLAMINAR FRACTURE TOUGHNESS OF GRAPHITE/EPOXY COMPOSITE LAMINATES. Interlaminar fracture toughness (IFT) characteristics of graphite/epoxy laminates were evaluated in tests on specimens with different tough adhesive interlayers. An artificial interlaminar edge crack was forced to propagate under two modes: separation, and shear. Results indicated that the interlayer, located in front of an existing flaw, may increase IFT more than sixfold compared with an uninterleaved brittle-matrix composite reference. The effect was stronger in the separation mode than in the shear mode, and seems to increase with thickness of the interlayer. (Edited author abstract) 15 refs.

**080211 EFFECT OF HIGH TEMPERATURE SPIKES ON A CARBON FIBRE-REINFORCED EPOXY LAMINATES.** Carbon fiber-reinforced epoxy composite laminates were exposed to programs of temperature and humidity intended to represent the high temperature excursions (thermal spikes) caused by ground-reflected engine efflux experienced by VTOL aircraft. Measurement of the laminate weight change during the tests indicated a change in the laminate moisture kinetics resulting in increased moisture equilibrium levels at spike temperature up to 175°C. Spiking at temperatures of 200-300°C showed a marked loss of laminate weight which cannot be attributed to loss of water alone. Permanent damage such as cracking was evident in some cases. The contribution of moisture to laminate degradation is discussed. (Author abstract) 8 refs.

**080213 COMPRESSIVE PROPERTIES OF BRAIDED AND WOVEN CARBON FIBER-EPOXY COMPOSITES AFTER LOW VELOCITY IMPACT.** The reduction of the compressive properties (residual compressive strength and strain) of braided or woven carbon fiber-epoxy composites were not as sensitive as the unidirectional prepreg laminates, when subjected to low velocity impact, as the results of this study indicated. Also, unidirectional prepreg laminates hybridized with braided or woven structure layers did not show any improvement in the compressive strength, as shown by this study. The delaminated areas after impact were measured by using ultrasonic B-Scan, C-Scan and photomicrograph, and the damage area were then correlated with the strain energy release rates  $G_{IC}$ . **080214 EVALUATION OF CARBON FIBER REINFORCED CORROSION RESISTANT PLASTIC LAMINATES.** Carbon fiber reinforcement was evaluated in corrosion resistant plastic laminates to determine its suitability as a surfacing mat. Chemical resistance testing was done according to ASTM C-581 in order to compare the corrosion resistance of reinforced laminates containing carbon fiber veil to glass veil and to non-woven polyester veil. The corrosion resistant resin used as the matrix was a high heat distortion temperature vinyl ester resin. The chemical environments included hydrofluoric acid because it is known to attack glass fibers. Other acids, bases and solvents were included in order to determine overall chemical resistance of carbon fiber reinforced plastic laminates. (Author abstract) 1 ref.

**080215 MICROGRAPHIC STUDY OF BENDING FAILURE IN FIVE THERMOPLASTIC-CARBON FIBRE COMPOSITE LAMINATES.** The local deformation and failure sequences of five thermoplastic matrix composites were microscopically observed while bending the samples in a fixture attached to a microscope stage. The thermoplastics are polycarbonate, polysulphone, polyphenylenesulphide, polyethersulphone and poly-

theretherketone. The composites made from these plastics contain a variety of carbon fibres with similar properties and have fibre volume fractions ranging from 32 to 66%. Comparison is made to an epoxy matrix composite, 5208-T-300. The thermoplastic composites failed by abrupt longitudinal compression buckling of the outer ply. Micrographs reveal typical fibre kinking associated with longitudinal compression failure. Curved fracture surfaces on the fibres suggest they failed in bending rather than direct compression. Delamination was suppressed and the delamination that did occur was the result of compression buckling rather than vice versa. Microbuckling also caused ply splitting, transverse ply shear failure, fibre tensile failure, and transverse ply cracking. (Edited author abstract) 8 refs.

**080218 NEUE MATERIALIEN UND IRE EINSATZMOGLICHKEITEN.** [Carbon Fiber Surfacing Mats: New Materials and Their Possible Applications]. Carbon fibers used for the manufacture of surfacing mats are a relatively new, flake-like material which is both light in weight and low-priced and yet has properties - electrical conductivity, thermal conductivity, chemical resistance, high strength - which differ basically from those of other woven and unidirectional materials. The use of surfacing mats for the production of isotropic composites necessitates a much simpler process than that required for the production of pseudo-isotropic laminates which must be reinforced in four or more directions. The mats can be used as load-distributing layers in conjunction with woven and unidirectional fabrics in order to produce the necessary reinforcement in directions other than those which bear the main load. (Edited author abstract). 8 Refs. In German.

**080219 INFLUENCE OF FIBRE STACKING SEQUENCE ON THE HIGH VELOCITY IMPACT RESPONSE OF CFRP.** The work presented examines the influence of the laminate stacking sequence on the high velocity impact resistance of CFRP. Attention is also given to examining the effect of replacing the  $\pm 45^\circ$  layers in a  $(0^\circ, \pm 45^\circ)$  composite by a woven fabric, a technique known to enhance the low velocity impact resistance of CFRP. The laminates were manufactured from pre-impregnated sheets of Grafil XA-S high strength surface-treated carbon fibers in Ciba-Geigy BSL 914C epoxy resin. Four of the panels were prepared from sheets of 0.125 mm thick pre-impregnated unidirectional tape stacked in the desired manner. These panels are referred to as non-woven laminates. The remaining laminates were manufactured by replacing the  $45^\circ$  plies in two of the  $(0^\circ, \pm 45^\circ)$  laminates by a five-shaft satin woven fabric. These

composites are referred to as mixed-woven laminates. The results suggest that mixed-woven laminates are well suited to conditions where the propagation of high velocity impact damage must be limited to a region local to the point of impact. Conversely, in circumstances where a higher perforation resistance is required it may be necessary to use a more conventional non-woven composite. 9 Refs.

Compression Molding See Also PLASTICS SHEETS—Sheet Molding Compounds.

**080221 COMPRESSION MOLDING OF COMPOSITES: MOLD HEATING SYSTEM DESIGN.** In compression molding of composite parts, it is important to minimize the temperature variation in the part during processing for consistent quality. A mold heating analysis and optimization scheme has been developed that allows computation of temperature variation on the mold/part surface, and optimizes the location and power of heaters. The heat transfer coefficients for a given mold can also be theoretically calculated. The experimental data compared well with theory and provide a satisfactory validation of the analysis. The present work provides a useful tool to a design engineer and allows the mold heating system design on a scientific basis, thus eliminating the trial and error approach. (Edited author abstract). 9 Refs.

Conductive

**080222 SIMULATION OF THE PERCOLATION THRESHOLD IN METAL FIBRE LOADED CONDUCTIVE POLYMER COMPOSITES.** It has been generally observed that in metal loaded polymer composites, as the volume fraction of metal is gradually increased, a sharp upturn in the volume conductivity occurs when the volume fraction reaches a certain critical value. It is difficult to observe the percolation threshold experimentally. If a fibre loaded composite is inspected under the microscope, numerous successive planes must be examined to trace even a single contact, and the scanning of a sample of ordinary size across the electrode gap becomes impractical. In view of the above difficulties the author has devised a large-scale model of the electrical behaviour of a fibre-loaded composite which allows the onset of percolation to be observed directly. The critical volume fraction is readily estimated for a given aspect ratio. The article describes the construction of the model and the results achieved. 6 Refs.

Crack Propagation See Also COMPOSITE MATERIALS—Fiber Reinforced.

**080224** ACOUSTIC EMISSION DURING FRACTURE OF SHORT GLASS FIBER REINFORCED POLY(VINYL CHLORIDE). The fracture mechanics approach and acoustic emission (AE) analysis have been coupled in an investigation of slow crack growth of short fiber reinforced poly(vinyl chloride). It was found that AE occurs during less than one percent of the time of crack growth suggesting that so-called continuous crack propagation is based on discontinuous microscopic damage. The time dependence of various AE parameters exhibits a good linear relationship with crack speed. For a unit of newly created fracture surface, a constant amount of acoustic energy is released independent of crack speed. At very low speeds, below  $3 \cdot 10^{-3}$  mm/s, a change in mechanism from pure matrix related to fiber related crack growth is observed, which is also reflected by a change in the amplitude distribution of the AE events. (Author abstract) 19 refs.

**080225** SLOW CRACK PROPAGATION IN A HEAVILY-FILLED PARTICLE REINFORCED EPOXY RESIN. The fracture property of two proprietary composite dental restorative materials and a model composite system were studied to determine the effects of filler concentration, exposure to water, and particle/polymer adhesion on subcritical crack propagation. Particle content ranged from 36 to 60 volume percent. The double torsion (DT) test was used to measure relationships between the stress intensity factor ( $K_I$ ) and the speed of decelerating cracks or the rate of loading in dry and wet materials in air at laboratory conditions. Materials with weak particle/polymer interfaces fractured by continuous crack growth in both dry and wet conditions. Observations on fracture surfaces indicate that low velocity cracks ( $< 10^{-5}$  s) propagate through regions of high stress concentrations (interfaces, corners, pores) while at higher crack velocities failure occurs by a combination of interparticle and transparticle fracture. (Edited author abstract) 22 refs.

**080226** COMPORTEMENT SOUS MICRO-ONDES (2.45 GHz) DE COMPOSITES RESINE EPOXYDE - NOIR DE CARBONE. [Microwave (2.45 GHz) Effects on Epoxy Resin/Carbon Black Composites]. Continuous or pulsed microwaves (2.45 GHz) are used to activate crosslinking of epoxy/carbon black composites. A complete study, taking into account the average electrical power of the microwave beam and the concentration of carbon black, has been carried out; in case of discontinuous emission, the period and the pulse length are also considered. The main results are: the same structural changes as for the pure resins are observed; in pulsed mode two types of relaxation are working; the first,

related to the oscillations of the dipoles (dipolar relaxation) at 2.45 GHz, and the second which concerns the mobility of short chain segments with maxima of efficiency at characteristic frequencies of the mode of emission; when the concentration of carbon black is increasing, an energetic transition takes place in the crosslinked state with a maximum of absorption of microwaves, at a concentration lower than the percolation threshold. ## Curing

**080227** RAPID TEST FOR EVALUATING THE DEGREE OF CURE IN CFRP COMPOSITES. A noncontact optothermal method is described for possible application to routine industrial evaluation of the degree of cure in polymeric composites. The surface of the part is heated by a laser beam or other radiative source while its temperature evolution is continuously monitored with an infrared detector. A strong exothermal peak is observed when the material is partially or totally uncured. Changes in the signal shape related to variations of the part geometry or environmental conditions are minimized by a differential approach comparing subsequent heat cycles on the same area. Results obtained with cured or uncured graphite-epoxy prepreg sheets are presented. (Author abstract) 17 refs.

Krapez, J.C. (Natl Research Council Canada, Boucherville, Que, Can); Cielo, P.; Cole, K.; Vaudreuil, G. *J Therm Anal* v 32 n 6 Nov-Dec 1987 p 1859-1865.

**080228** MICRODIELECTRIC MONITORING OF PREPREG CURE. The feasibility of using a microelectric sensor to characterize the cure behavior of a commercial prepreg roving was investigated. Chemical and physical characterization methods were first used to determine the uniformity of the prepreg material. Thermal, dynamic mechanical, and dielectric methods were then utilized to monitor the cure cycle. The dielectric response was found to be independent of the glass fibers of the prepreg and to show reproducible changes in the early part of cure over a temperature range of 80 to 135°C. The manufacturer's recommended cure temperature of 121°C (250°F) was found to correspond to the onset of the ultimate glass transition of the material. Variations in the dielectric response in the latter part of cure at this temperature and above were attributed in part to this event. (Author abstract) 7 refs.

**080230** VISCOELASTIC RESPONSE OF UNIDIRECTIONALLY REINFORCED THERMOPLASTIC COMPOSITES TO OFF AXIS DEFORMATION.

Measurements of dynamic viscoelastic in-plane shear modulus have been made for unidirectional carbon fiber composites with amorphous engineering thermoplastics as the binder resins. The viscoelastic response is modeled by a three-phase, finite-element model in which fiber placement in the plane perpendicular to the fiber axes is largely disordered. In the model, fibers tend to chain with the distance of closest approach dictated by several factors, including the tendency for the resin to wet the entire fiber surface. Polished section microscopy supports the assumed microstructure. The model includes an adsorbed primer layer at the fiber interface with perturbed viscoelastic response. The model is useful throughout the temperature range up to and including the glass transition of the binder resin. (Author abstract) 20 refs.

## Degradation

**080231** HYGROSCOPIC EFFECTS IN ARAMID FIBER/EPOXY COMPOSITE. Hygroscopic effects in aramid fiber composites are assessed semiempirically using a combination of micromechanics models and experimental data. It is pointed out that the in situ moisture concentration of the fiber should be known, as it affects diffusional as well as expansional properties. The micromechanics models for moisture absorption indicate that the in situ moisture concentration is lower than the bulk value. The interfacial radial stress can be tensile in wet unidirectional composites, and ply cracks are shown to increase moisture diffusion in laminates. (Author abstract)

Hahn, H.T. (Pennsylvania State Univ, University Park, PA, USA); Kim, K.S. *J Eng Mater Technol Trans ASME* v 110 n 2 Apr 1988 p 153-157.

**080232** DEGRADATION BEHAVIOR OF BULK MOLDING COMPOUND IN ACID ENVIRONMENTS. The aim of this study was to develop a new BMC (Bulk Molding Compound) with low molding shrinkage and high acid resistance. The resin system used in this study was a novolac type epoxy resin with low shrink additive and the reinforcements used were glass, carbon and aramid fibers. Firstly the mold shrinkage, the heat distortion temperature and the electric resistance of BMC were measured as the functional properties. The immersion test was carried out in a bath with a mixed solution of 25wt percent H<sub>2</sub>SO<sub>4</sub> and 7.5 wt percent HNO<sub>3</sub> at 65°C up to 3000hr. The weight change and the reduction of mechanical properties were measured in order to examine the degradation mechanism of BMC. It is concluded that Hybrid BMC which are reinforced by glass, carbon and aramid fibers show the excellent functional properties. The acid resistance of BMC developed in this study is much higher than that of BMC in which the matrix is the epoxy resin with high acid resistance. (Author abstract). 7 Refs. In Japanese.

**080233** MODEL FOR PREDICTION OF THE ELASTIC RESPONSE OF REINFORCED MATERIALS OVER WIDE RANGES OF CONCENTRATION. A model for the prediction of the elastic response of reinforced materials over wide ranges of concentration is presented. The method is based on the mathematical analogy between the motion of particles suspended in viscous media and the elastic deformation of solids. The system is locally described by linearized forms of the elastic moduli. The validity of these relations is then extended to all concentrations under the assumption that

any new portion of filler 'sees' the existing structure as a noninteracting homogeneous matrix. The method predicts the behavior of reinforced materials with solid spherical inclusions and foams over wide ranges of concentration. The model, free from adjustable parameters, shows excellent agreement with existing experimental data. The extension of the method to other inclusion geometries is straightforward. (Author abstract) 30 refs.

## Electric Conductivity

**080234 ELECTRICAL CONDUCTIVITY OF POLYETHYLENE-CARBON-FIBRE COMPOSITES MIXED WITH CARBON BLACK.** The influence of the mixing procedure of the additives and material preparation is examined with regard to conductivity. The use of two filler types combines the conducting features of both. Thus, while fibers provide charge transport over large distances (several millimeters), carbon black particles improve the interfiber contacts. Results are discussed with reference to simple electrical models. For composites in which the segregated carbon black-polyethylene component lies above the percolation threshold the electrical interfiber contacts are activated through carbon black particle bridges, leading to a conductivity rise. This effect is more relevant in the case of shorter fibers. Processing involving fiber orientation such as in injection molding decreases the conductivity. (Edited author abstract) 12 refs.

**080235 VAN DER PAUW MEASUREMENT OF METAL FIBRE ORIENTATION IN A PLASTIC-METAL COMPOSITE.** Stainless steel fibers in ABS plastic form a composite with an anisotropic resistivity. Samples are rectangular shapes with uniform thickness. By assuming two principal resistivities and by using van der Pauw's technique, the authors find  $\rho_y/\rho_x$  hence fiber direction. Results for three sample geometries agree with the theoretical predictions of the fiber patterns and with x-ray data. Samples formed by a center sprue feed are best for fabricating large, uniform samples while samples with a large length to width ratio have the most uniform density and fiber orientation. Resistivity was also measured by the two-probe technique. (Edited author abstract) 23 refs.

Kinsler, Mark (Univ of Pittsburgh, Pittsburgh, PA, USA); Hmurcik, Lawrence V.; Patton, Joyce. *J Mater Sci* v 23 n 4 Apr 1988 p 1425-1430.

**080236 ELECTRICAL CONDUCTION PHENOMENA BETWEEN ADJACENT STAINLESS STEEL FIBRES IN A THERMOPLASTIC MATRIX.** In a programme designed to elucidate the fundamental mechanisms involved in electrical conduction through a polypropylene matrix filled with non-contacting stainless steel fibres, the current flow between two individual fibres orientated perpendicularly in a polypropylene bead has been studied. The fibre diameter was 22  $\mu\text{m}$  and the gap length was 100  $\mu\text{m}$ . The resistance at low voltages was five orders of magnitude lower than could be accounted for by assuming that homogeneous conduction had taken place with tabulated values of the volume resistivity of the matrix obtaining. Transmission optical microscopy revealed that during current flow, the greatest heating and degradation of the polymer did not take place along the shortest path between the fibres. (Edited author abstract) 14 refs.

Electric Properties See PLASTICS—Conductive.

## Environmental Testing

**080237 DURABILITY OF SiC FIBER REINFORCED EPOXY RESIN IN BOILING WATER.** SiC fiber and glass fiber reinforced epoxy resins (SiCFRP and GFRP), which were fabricated by using matching male and female metal molds, were immersed in boiling water for the periods from 5 to 500 hours. The amount of water absorption of SiCFRP was less than that of GFRP, and those of SiCFRP and GFRP immersed for 100 hours were 38.5 mg/cm<sup>3</sup> and 76.6 mg/cm<sup>3</sup>, respectively. The amount of water absorption at the time when the width of SiCFRP specimen began to increase was 9.5 mg/cm<sup>3</sup> against 44 mg/cm<sup>3</sup> of that of GFRP. ILSS retention of SiCFRP immersed decreased with increasing immersion time, while the diameter, weight and tensile strength of SiC fiber were not affected at all by immersion in boiling water up to 500 hours. The ILSS retention of 74% for SiCFRP immersed for 100 hours was almost the same as that of 76% for GFRP. The reason of such low durability of SiCFRP to hot water was interpreted as the bond between the fiber and resin was weak to water because the surface of SiC fiber was not treated. (Author abstract) 6 refs. In Japanese.

## Extrusion

**080238 THEORETICAL AND EXPERIMENTAL STUDY OF FIBRE ATTRITION DURING EXTRUSION OF GLASS-FIBRE-REINFORCED POLYPROPYLENE.** On the basis of the experimental observations described in previous work by authors, a model has been proposed to analyse the phenomenon of fiber breakage taking place when granules of short-fiber-reinforced thermoplastics are processed in an extruder. This model essentially determines the bending moment experienced by a single fiber, anchored at one end, due to drag forces produced by the flow of molten polymer past it. This model clearly brings out the effects of molten film thickness, screw speed, viscosity of the polymer melt and the fiber orientation relative to the flow direction. It is postulated that the model provides a mechanism for the breakage of fibers exposed by melting of polymer at the solid bed-molten polymer interface. For fibers which are free to move in the molten polymer, buckling introduced by the shearing motion of the molten polymer, as predicted by the Forgacs and Mason model, is responsible for their attrition. Using the extrusion data of ref. 1, the results of the combined use of the two models show good agreement with the experimental observations, in particular the fiber length distribution of various stages of extrusion. This agreement is observed in spite of several assumptions inherent in the model. Finally, the effect of fiber agglomeration on the attrition phenomenon is also studied. (Edited author abstract) 13 refs.

## Fabrication

**080239 TOOLING UP FOR A COMPOSITE FUTURE.** Choosing the right material for mold tooling can be critical to the productivity and performance of a composite structure. Selection involves a complex balancing of many factors - initial acquisition cost, lead time, maintenance/repair feasibility and costs, compatibility with cure cycle, porosity, dimensional stability, number of parts to be produced, energy/labor demands, ease of modification, and others. The relative weighting of these different factors determines which material is best, because no single material has been universally accepted as the all-purpose tooling material. Various types of mold materials and selection factors are discussed.

English, Lawrence K. (Materials Engineering, Cleveland, OH, USA). *Mater Eng (Cleveland)* v 4 n 9 Sep 1987 p

69-71.

**080240 PULTRUSION PRESSES AHEAD.** Pultrusion is one of the better established volume production techniques for advanced composites, but ironically, also one of the least well understood. The Runcorn-based company Fibreforce, has produced a design manual for pultruded composite components which will be available direct from the company. The manual begins with an explanation of the pultrusion process, which produces profiles in composite materials by pulling resin-impregnated fibers through a heated die, and goes on to outline some of its capabilities. The manual then goes on to outline the benefits and limitations of the process. These and other aspects of the subject are discussed in the article.

**080242 SCHADENSMECHANIK FASERVERSTAERKTER KUNSTSTOFFE EIN UEBERLICK.** [Damage Mechanics in Fiber-Reinforced Plastics. A Review]. Failure mechanisms in composite laminates are quite different from those in homogeneous materials. While metal materials under fatigue fail as a result of initiation and growth of a single dominant crack, composite laminates can sustain many cracks before ultimate failure. Damage in composites can be any of the following: fiber breaks, resin cracks, interfacial debonds, and delaminations between the plies of the laminate. All these cracks are not separated but interconnect. Much of these damages occurs long before the ultimate failure. The process of composite laminate damage mechanisms under static and fatigue loading is described. It is known that this fracture process involves sequential accumulation of damage, in form of matrix-dominated transverse and longitudinal cracking and delamination. (Author abstract) In German. 11 refs.

**080243 EINFLUSS VERSCHIEDENER PARAMETER AUF DIE SCHADENSENTWICKLUNG.** [Influence of Different Parameters on Damage Development]. A comprehensive test program in the framework of damage mechanics under fatigue loading was performed to investigate the influence of laminate stacking sequence, fatigue loading conditions and environmental conditions such as temperature and/or humidity on damage development and fatigue properties. Results of these investigations and appropriate measuring techniques are discussed. (Edited author abstract) In German. 23 refs.

**080244** SCHAEDIGUNGEN IN ATLASGEWEBELAMINATEN UNTER STATISCHER UND SCHWINGENDER BEANSPRUCHUNG. [Damage to Woven Satin Laminates Subjected to Static and Fatigue Loading]. The mechanical properties and the damage mechanisms of a laminate with four plies and unsymmetrical stacking sequence manufactured from eight-end sateen weave prepreps were determined in static tests as well as tension-tension and tension-compression fatigue tests. The inplane shear properties were also examined. The damage initiation and propagation up to failure were observed by optical microscope and other nondestructive testing methods. (Edited author abstract) In German. 13 refs.

**080245** ACOUSTIC EMISSION ANALYSIS IN PLASTICS. A survey of some of the developments in the characterization of failure mechanisms in particle filled and reinforced polymers by means of the acoustic emission measuring technique indicates the fields of application for this method under conditions of static and quasi-static tensile stress. Furthermore, a report is given on AE measurements performed on a modified hydraulically assisted testing machine on specimens subject to fatigue stress. The acoustic emission rate measured when testing short glass fibre reinforced polycarbonate under tensile fatigue stress gives an early indication of the imminent failure of the specimens. (Edited author abstract) 31 refs. In German and English.

**080246** MATRIX CONTRIBUTION TO FATIGUE BEHAVIOR OF GLASS REINFORCED POLYESTER COMPOSITES. The objective of this study was to investigate the influence of polyester toughness on longitudinal fatigue behavior of glass-fiber reinforced composites. The results show that at a high fatigue stress, the rate of increase in fatigue life with respect to decrease in fatigue stress is nearly equal for composites studied. However, in a stress range between 35 to 45 percent of the ultimate strength, the rate of increase in fatigue life with decrease in fatigue stress improves with use of the ductile polyester resin in the composite. In general, the final failure of the laminate was a combination of debonding and fiber breaks. The study shows that the toughness of the polyester helps in delaying the initiation of microdamage and offers a reliable index for measuring contribution of the matrix in FRP under fatigue loading. (Edited author abstract) 8 refs.

**080247** COMPOSITES TAKE THE STRAIN. Composite strands made up of pultruded fiber reinforced rods are promising candidates for use as tension members in structural applications, for example in suspension bridges or as tethers for oil platforms. This article describes a test program which aims to produce performance and design data for the use of advanced composites in this demanding application. Recognizing the growing interest in lightweight strength members, British Ropes began an investigation into the use of high strength fibers and fiber composites, with particular emphasis on structural applications. The performances of aramid, carbon and glass fiber reinforced plastics products are being evaluated against the more traditional steel strand.

**080248** IMPACT PROPERTIES OF NATURAL FIBRE COMPOSITES. Little analysis has been made to correlate the impact behavior of natural fiber composites with the fiber properties. It is with this view that the present study on the impact properties of natural fiber composites has been undertaken. Unidirectionally aligned fiber/polyester composites containing ca. 0.5 volume fraction of sisal, pineapple, banana and coir fibers were prepared from unsaturated polyester prepreps. An attempt has been made to explain the variation in impact properties of various natural fiber composites in terms of microfibrillar angle of the fiber. 12 refs.

**080249** NEW MATERIAL CONCEPTS - FIBRE COMPOSITES SUPERIOR TO METALS. Asea Plast, with headquarters in Ojebyn outside Pitea in northern Sweden, is developing and manufacturing several interesting products having a lower weight and overall cost than corresponding products fabricated from traditional metals. The manufacture of tanks, pressure vessels, propeller shafts for trucks, leaf springs, and anti-armor weapon barrels is described. The use of CAD and expert systems is briefly outlined.

Barnheim, Bjorn. *ASEA J* v 60 n 5 1987 p 4-7.

**080250** CONTROLLED ENERGY DISSIPATION IN FIBROUS COMPOSITES. I. CONTROLLED DELAMINATION. Delamination mechanisms in continuous fiber reinforced composites were investigated. The concept of controlled interlaminar bonding (CIB) is proposed as a guideline for preparing fiber-epoxy composite laminates with enhanced fracture toughness without significant degradation in strength properties. The interlaminar bonding was manipulated by several specialized techniques including insertion of delamination promoters and surface modification of laminae. Results indicated that the plane-strain fracture toughness of E-glass-epoxy laminates could be improved by inserting perforated interlaminar films of aluminum, paper, polyester and polyimide, and fabrics. Experimental results from several composite systems are presented and discussed along with post-failure analysis data. (Edited author abstract) 19 refs.

**080251** HIGH PERFORMANCE FIBER COMPOSITES WITH SPECIAL EMPHASIS ON THE INTER-FACE. The literature on high performance composites containing high strength, high modulus fibers, including glass, carbon, and aramid fibers in resin matrices is reviewed with special emphasis on the interface between fiber and matrix. The physical chemical properties of the various fibers and resin matrices are analyzed, and the manufacturing processes for making composites summarized. The effects on composite properties of fiber diameter, fiber length, fiber volume, fiber orientation, and the presence of voids are discussed. To obtain good adhesion between fiber and matrix, which is essential in high performance composites, physical interaction at the interface is important, but chemical reaction between fiber surface and matrix is desirable for optimal tensile and modulus properties. (Author abstract) 102 refs.

**080252** METHOD OF ESTIMATING THE ADHESION BETWEEN POLYMER AND FILLER OF FIBER REINFORCED COMPOSITE MATERIALS. The distribution of fiber lengths in injection moldings of fiber reinforced composite materials was almost normal. Under the conditions for normal distribution, i.e.,  $3\sigma$  (standard deviation)  $\approx L$  (average length), the equation of tensile strength reported by J. Yamaki becomes linear

with regard to the parameter  $\phi$  which estimates the adhesion between filler and polymer and aspect ratio. According to this equation, the  $\phi$  values of PC/GF and PP/GF prepared under various adhesive conditions were obtained. By using H.L. Cox's tensile strength equation assuming complete adhesion,  $\phi_0$  was then calculated. The results probably make possible the estimation of the effects of surface modifiers on adhesive conditions and the degree of adhesion. (Author abstract) 12 refs. In Japanese.

**080253** CASE STUDY: TRANSPORT APPLICATIONS OF FIBRE REINFORCED PLASTICS - A CONSORTIUM APPROACH. This paper describes how a consortium of materials suppliers and end users selected components for the application of fibre-reinforced plastics composites in order to expand research into five specific areas. A brief outline of the ensuing research work on each component is given. (Author abstract) 1 ref.

Hughes, D. (Natl Engineering Lab, East Kilbride, Scotl). *Plast Rubber Process Appl* v 8 n 2 1987 p 69-78.

**080254** CRACK TIP HEATING IN SHORT-FIBRE COMPOSITES UNDER FATIGUE LOADING CONDITIONS. Crack tip heating in cyclically loaded short-fiber polymer matrix composites occurs by a combination of hysteretic heating and frictional heating. While the former mechanism is caused by plastic and viscoelastic deformations within the polymeric matrix, the latter is due to interfacial friction between matrix and fibers, and crack surface interference associated with crack closure. The relative contribution of these two principal mechanisms depends upon a number of variables including the viscoelastic and plastic characteristics and frictional properties of the matrix polymer, the degree of interfacial adhesion, the fiber content and fiber orientation distribution and the loading conditions. The results confirm that even in a tension/tension loading mode, frictional heating may play a dominant role, at least in some systems. (Author abstract) 22 refs.

**080255** STUDY OF MODEL POLYDIACETYLENE/EPOXY COMPOSITES. A model composite has been prepared consisting of a polydiacetylene single-crystal fiber in an epoxy resin matrix. The strain at points along the length of the fiber has been measured, using Raman spectroscopy, as a function of matrix strain and the post-cure temperature of the matrix. Good quantitative agreement has been found between the behavior of the cold-cured system and the shear-lag model of Cox. The critical length of the fibers was measured as a function of fiber diameter and compared with recent calculations using finite difference methods. Higher post-cure temperatures have been shown to lead to compressive deformation of the fibers due to matrix shrinkage on cooling. The deformation is manifest as twinning, which disappears reversibly during tensile deformation. The amount of matrix shrinkage was determined by measuring the level of strain required to remove the twins. (Edited author abstract) 18 refs.

**080257 OBRADA PLASTICNIH VLAKNASTIH KOMPOZITA VODENIM MLAZOM.** [Machining of Fiber Composites with Water Jet]. With the growing use of composite materials, there is also an increase in interest for suitable machining possibilities, including nonconventional machining processes. This paper presents a description of water jet machining. Its significance and field of application. This process requires small cutting forces, and compared with other processes it is a 'cool' process. For this reason, water jet is used mostly to machine composites with or without fiber, rubber, glass or stone. By adding the abrasive materials into the water jet, this process can also be used for the machining of metals which are difficult to machine. (Author abstract) 16 refs. In Serbo-Croatian.

**080258 HIGH PERFORMANCE REINFORCEMENT FABRICS.** Commercial fiber reinforced plastics generally employ woven reinforcement fabrics to facilitate ease of handling. However, these fabrics do not fully realise the reinforcement potential of the fibers. The level of translation of the fiber properties into the composite structure, and the conformability to complex curvatures, are limited by the harshness of the weaving process and the crimp geometry of the weave. Over recent years, a number of alternative reinforcement fabrics have become available which allow more complete realization of the potential of the fibers. This paper reviews those fabrics. The paper first considers singly reinforcement fabrics (triaxial weaves, braids, knitted and non-woven materials) and then multi-ply reinforcements (stitch interlocks, through-plane weaves, and through plane random reinforcements). (Author abstract) 150 refs.

**080259 MELT RHEOLOGY OF FILLED THERMOPLASTICS.** The rheological properties of filled thermoplastic melts are reviewed. The response of filled melts in steady, dynamic and transient shear follows as well as uniaxial extensional flows are studied in terms of three important material variables: the volume concentration of the fillers, filler size and shape, and polymer-filler interfacial characteristics. The fillers, the shapes of which strongly influence the overall rheology, especially the elastic behavior, can be classified into those having directionality such as fibers and those without it which we denote as particles. Within each category, increasing filler loading increases the viscous dissipation and elastic energy storage capacity of the system eventually giving rise to a yield stress at high concentrations. Decreasing filler size increases the importance of interfacial interactions and generally results in larger value of viscous dissipation and elasticity. The ratio of the normal stress difference to shear stress is smaller for a particle filled system than for the pure melt, but is larger for a fiber filled melt compared to the pure melt. **080260 EFFECTS OF FILAMENT ORIENTATION ON THE LOSS FACTOR OF LAYERED COMPOSITE BEAMS - LAYERED COMPOSITE BEAMS REINFORCED IN TWO DIRECTIONS.** A damping material reinforced in two directions has been fabricated. The matrix of the damping material is an epoxy resin and a stainless steel filament is used as the reinforcing material. Experimental results show that the modulus of elasticity is more sensitive to the orientation of the reinforcing

filament than the loss factor and that the ability of the damping materials is improved by using a filament with a high modulus of elasticity for the damping material. The ability of the damping material reinforced in two directions is improved in comparison with the results for a damping material reinforced in one direction. (Edited author abstract) 4 refs. In Japanese.

**080261 POLAR-POLAR INTERACTION AND BOUNDARY PHASE STRUCTURE BETWEEN REINFORCEMENT AND MATRIX IN A POLYMER COMPOSITE.** This paper describes an attempt to correlate the nature of polar-polar interaction between the reinforcement and matrix in a polymer composite with the boundary phase structure formed in contact with the reinforcement. It is shown by analyzing the mechanical dispersion data that the reinforcement-matrix interaction of Kevlar fiber reinforced poly(hydroxypropyl ether of bisphenol A) (P) is increased by blending poly(ethylene oxide) (E) or poly(ethylene adipate) (A) as a part of matrix, and that E is more efficient than A for the increase of the interaction. These results can be supported at the molecular level from the inspection of the Fourier transform infrared spectra on the Kevlar fiber coated with matrix polymers and the mixture of matrix polymers with benzanilide, which is used as a model compound of Kevlar fiber. (Edited author abstract) 14 refs.

**080262 THE STRESS-STRAIN CURVE IN FIBRE REINFORCED PLASTICS.** Recently, 'critical' composites have been made to test traditional fibre reinforcement theory. These critical composites contain short aligned fibres. They produced results which did not fit the theories. In this paper these theories are briefly reviewed and extended to include the case of fibres with debonded ends (such debonding could take place during manufacture). It is shown that such debonding will lead, under certain circumstances, to straight line stress-strain plots. (Edited author abstract). 17 Refs.

**080263 FASERVERBUNDWERKSTOFFE (TEIL 1): FASERWICKELN MIT PREPREGS UND GMT-VERARBEITUNG.** [Fibre Composites, Part 1]. By virtue of their properties, fibre composites, which have so far been used chiefly in the classic light-weight construction sectors of the aviation and space industries, also have interesting applications to offer in mechanical engineering. This, however, calls for the development of new processes to permit sufficiently high item numbers to be rationally produced. In many cases, it is the impregnation and curing of the matrix that determine the cycle time. Direct impregnation also gives rise to qualitative shortcomings. The impregnation process can be eliminated by processing prepregs. Furthermore, cycle time can be drastically reduced by using a thermoplastic matrix. The processing methods - both winding and compression moulding - must, however, be adapted to the new materials. This is illustrated with the example of filament prepreg winding and GMT (glass mat reinforced thermoplastics) processing. (Edited author abstract). In German.

**080264 APPLICATION OF X-RAY TOMOGRAPHY IN NON-DESTRUCTIVE TESTING OF FIBRE REINFORCED PLASTICS.** Medical X-ray tomography has been used for non-destructive evaluation (NDE) of various types of polymeric products. Composites, carbon-graphites, fiber-reinforced aluminum, vulcanized rubbers and thermoplastics have been carefully examined in order to detect flaws, pores, voids and other imperfections in the materials. There is some evidence that medical

X-ray tomography can be a very sensitive instrument for registration of small density variation in polymers. (Edited author abstract). 24 Refs.

**080265 QUALITÄTSVERBESSERUNG DURCH VOLLSTÄNDIGE PROZESSKONTROLLE.** [Fiber Reinforced Composite Materials - 2. Improved Quality Through Automation and Refined Process Control]. Part 1 of this three-part series on fiber composites gave a description of the processing methods. In this, the second part, a full-scale process control system is presented, taking the example of prepreg processing. It starts with the control of prepreg manufacture. Image processing systems provide good service on account of their high performance and flexibility. A second quality check is required before the prepreps are processed in order to establish the influence of storage. It goes without saying that particular attention should be paid to the curing cycle. The finished component must then be subjected to controls once again. Nondestructive test procedures will permit 100 percent control in large-scale production in the future. (Edited author abstract). In German.

**080266 WIDE ANGLE X-RAY DIFFRACTION INVESTIGATIONS OF ORIENTATION OF CHOPPED FIBERS IN FABRICATED THERMOPLASTIC PARTS.** A method of determining fiber orientation in composites using wide angle X-ray diffraction (WAXD) is described. This approach is based upon examining the alignment of the highly oriented crystalline fibers. X-ray studies were carried out using Kevlar [poly(p-phenylene terephthalamide) (PPTA)] fibers suspended at a 0.31 volume fraction loading in a polycarbonate matrix. A pole figure device was used to determine the orientation distribution and average orientation factor of the PPTA crystallographic chain axes relative to reference axes located in the test specimen. We prepared ideally oriented uniaxial and biaxial composites as reference specimens using a compression molding machine. The fiber orientations in capillary extrudates, slit die extrudates, cold rolled sheets, and injection-molded specimens were examined by WAXD. The capillary extrudates showed uniaxial orientation but the slit die extrudates and cold rolled sheets exhibited biaxial orientation. Injection-molded specimens contained complex states of fiber orientation. (Edited author abstract). 14 Refs.

**080267 NEW LOW COST, HIGH PERFORMANCE REINFORCING FIBER BEING DEVELOPED.** Research and development are under way at the University of Wisconsin that may have a profound influence on the fiber-reinforced plastics (FRP) industry in three years' time. A new class of reinforcement fibers has been discovered, combining some of the best features of boron, carbon, etc., with the low cost of glass. A technique has been found for melt spinning high mechanical performance fibers from ceramic compositions that need not contain boron or silica. Young's moduli well over double that of E glass have been produced. The technique is termed redrawn inviscid melt spinning (RIMS). RIMS is a two-step process, each of which is very rapid (milliseconds). The first step, inviscid melt spinning (IMS), circumvents the need for high melt viscosity, thus eliminating the need of chain formers such as silica. A transformation takes place when the glassy IMS fibers are reheated and drawn to still finer fiber diameters - the second step of the process. 4 Refs.

**080268 MINERAL REINFORCEMENTS: NOW THEY HELP TO EASE ADDITIVE TIGHTNESS.** The synergism that improved nonfibrous fillers and reinforcements bring to resin systems is a well-told tale. But there is a new twist in that they are beginning to be used as substitutes for scarcer or more costly ingredients...without sacrificing product quality. For example, in polypropylene outdoor furniture loadings of 40 to 80 percent of calcium carbonate and talc provide the stiffness and ceramic-like feel needed in this application. And with persistent tightness in titanium dioxide, some low-cost fillers are being tailored for service as pigment extenders. Overall, the theme in nonfibrous materials continues to be improved performance at an affordable price. The class of reinforcements that does not occur naturally gets several new entries: glass reinforced plastics macrospheres and thermoset plastic fillers.

**080270 RELATION BETWEEN WORK OF FRACTURE AND FRACTURE TOUGHNESS OF SHORT-FIBRE REINFORCED POLYMERS.** On the basis of micromechanical failure mechanisms acting in short-fiber reinforced polymers the authors derive the crack resistance curve (R-curve) as a function of crack extension. With the conditions characterizing the point of crack instability, the critical crack extension and fracture toughness  $G_c$  are calculated. By comparing  $G_c$  to the work of fracture it is concluded that, depending on the relevant failure characteristics, two parameters are necessary to describe the failure behavior - the fracture toughness for crack instability or strength and the work of fracture as the energy necessary to drive the crack through the sample. (Edited author abstract) 4 refs.

**080271 EFFECT OF FIBER-MATRIX ADHESION ON THE FATIGUE FRACTURE OF GLASS-FIBER-REINFORCED POLY(VINYL CHLORIDE).** Fatigue crack propagation (FCP) of injection-molded glass-fiber-reinforced poly(vinyl chloride) was examined as a function of fiber-matrix adhesion (coupling) and fiber content at different load levels. Considering the entire FCP history, from crack initiation to critical propagation, it is shown that fatigue lifetime and fracture toughness of coupled composites increase with fiber weight fraction. Uncoupled material exhibits the highest fracture toughness at 10 wt% fiber, yet its fatigue life is considerably shorter. Damage analysis indicates that fiber debonding, pullout, and particularly fiber fracture seem to contribute to the higher fatigue lifetime noted in coupled composites.

The Crack Layer Theory is employed to describe the observed FCP behavior. The effective enthalpy to damage parameterizes the resistance of the composite to FCP in terms of the boserved mechanisms. (Author abstract) 14 refs.

**080272 FATIGUE BEHAVIOR OF PLAIN WOVEN GRP IMPROVED TO PREVENT FROM DAMAGE.** Measurements were made on the residual strength of glass-reinforced plastic (GRP) specimens and the strength of the constituting fiber strands in order to clarify the change in fiber strength during fatigue. It was found that the crack length obtained from A.A. Griffith strength agreed well with the predicted value calculated from the damage. Fatigue tests were made on the altered specimens whose weft strands were covered with polymer sheets. The warp strands were found to be protected from suffering damage by wefts at woven intersections. The fatigue strength increased by 2.26 times of the original value, and thus it was possible to prepare the cloth GRP of high fatigue strength. (Edited author abstract) In Japanese. 12 refs.

**080273 DYNAMIC MECHANICAL PROPERTIES OF STRUCTURAL GLASS FIBRE-EPOXY COMPOSITES.** Dynamic mechanical measurements at a frequency of 1 Hz have been made from 100 to 480 K on unidirectionally aligned composites of glass fibers and epoxy resin of diglycidyl ether of bisphenol A and 4,4'-diaminodiphenylmethane, prepared under two conditions: (i) by mechanically mixing without a solvent; and (ii) by mixing their solutions in methyl ethyl ketone. The composites show the same three relaxation regions as the pure epoxies, but their relative magnitudes differ. The glass transition temperature of the composite prepared by the first method is less than that of pure epoxy but of that prepared by the second method is greater. (Edited author abstract) 12 refs.

**080274 DETERMINATION OF THE ORIENTATION OF SHORT GLASS FIBERS IN SHEET MOLDING COMPOUND (SMC).** A computer based semiautomatic procedure has been developed to measure the fiber orientation on the surface of Sheet Molding Compound (SMC) plaques. The principal orientation direction and the Hermann's orientation descriptor were used to summarize the fiber orientation distribution. The results show that only slight orientation was produced in the SMC plaque with a centrally placed charge occupying 40 percent of the area of the mold. Plaque to plaque, top surface to bottom surface, and region to region variability in the fiber orientation were observed. The orientation of

fibers in the four quadrants of the same plaque differed significantly. (Edited author abstract) 16 refs.

**080275 NONDESTRUCTIVE METHOD TO DETERMINE MATERIAL PROPERTIES IN ORTHOTROPIC PLATES.** An electronic speckle pattern interferometer (ESPI) is used to determine modes of vibration in rectangular, orthotropic, free-free-plates; that is using a noncontact, nondestructive, optical method. It is shown, using the finite element method (FEM), that each of the first three modes of vibration in rectangular orthotropic plates has a strong dependence upon only one of the main material parameters, namely the in-plane shear modulus and the two Young's moduli, respectively. With this one-variable dependence it is a simple task to determine the effective material parameters. This method has several obvious advantages compared to the use of test bars and it can be extended to give a measure of the damping parameters and probably also be used for production control. Preliminary results are presented and discussed. (Author abstract) 7 refs.

**080276 WETTABILITY OF GLASS FIBRES WITH DIFFERENT SIZINGS AND THEIR ADHESION TO UNSATURATED POLYESTER MATRICES.** The wetting characteristics of unsaturated polyester resins on glass fibers with different sizings have been studied by contact angle determination periods. The styrene content of the matrix and the nature of the coatings result to be determinant in the wettability of glass fibers by the polyester matrices. Highest styrene content and styrene-soluble-coatings determine better wetting characteristics. Mechanical properties of the cured specimens and scanning electron microscopy on the fracture surfaces were also performed. Interesting correlations between the nature of the sizing agent and cohesive energy density with mechanical properties and fibre/matrix adhesion were found. (Author abstract) 7 refs.

**080277 ACOUSTO-ULTRASONIC TECHNIQUE FOR PREDICTING FATIGUE BEHAVIOUR OF GLASS-FIBRE REINFORCED PLASTICS.** Fatigue data for glass-fiber reinforced plastics (GRP) have even wider scatter due to inherent material and manufacturing anomalies associated with GRP. Hence, non-destructive evaluation (NDE) of fatigue behavior of GRP assumes greater significance. This paper describes an acousto-ultrasonic NDE technique, which is a combination of acoustic emission technique and ultrasonic technique, for the prediction of fatigue behavior of GRP composites. The results of the study show that the parameter commonly known as stress-wave-factor (SWF) can easily be used with fullest confidence to predict fatigue behavior of GRP composites. (Edited author abstract) 3 refs.

**080278 ULTRASONIC DETECTION OF PERCENTAGE OF VOIDS IN GLASS-FIBRE REINFORCED PLASTIC CYLINDER.** This paper describes the results of a study undertaken to determine the relationship between ultrasonic attenuation and percentage of voids in glass-fiber reinforced plastic composite cylinders using an ultrasonic test instrument and metallurgical microscope. The validity of graph upto certain confidence level has been determined by simple library program using a computer. Correlation indicate that the ultrasonic attenuation can predict the percentage of voids

in GRP cylinder. Thus, by calculating the attenuation values one can fix the confidence limits of accepting or rejecting the material. (Author abstract) 6 refs.

**080279 MECHANISMS OF FATIGUE FRACTURE IN SHORT GLASS FIBRE-REINFORCED POLYMERS.** Fatigue-crack profiles and fracture surfaces of several short glass fiber-reinforced polymers were examined to gain insight into the mechanisms of cyclic damage and fatigue-crack propagation in these materials. Several distinctly different features were noted between fracture surfaces generated by stable fatigue crack growth and those produced by monotonic or unstable fracture. Among the most significant differences were the higher degree of single and multiple fiber fracture generally observed on stable fatigue-crack growth fracture surfaces, and the variations in the interfacial failure site in well-bonded systems. While the former effect is attributed to the occurrence of crack closure and the build-up of compressive stresses in the crack-tip damage zone during unloading, the differences in the interfacial bond strength. No features could be identified that would allow a quantitative correlation between the applied stress intensity factor level or the crack growth rates and characteristic fracture surface details. **080280 FATIGUE CRACK PROPAGATION IN GLASS-FIBRE AND GLASS-SPHERE FILLED PBT COMPOSITES.** Fatigue crack propagation has been studied in injection-molded plates of unfilled PBT and composites filled with short glass fibers of varying length and in different volume fractions. Materials filled with glass spheres and short glass fibers have also been investigated. The influence of crack propagation direction and of the microstructural composition on crack speed is discussed. It is found that a model which accounts for the fiber orientation distribution, the skin-core morphology and the change in failure mechanisms due to variations in the fiber length and aspect ratio can explain the differences observed in crack propagation behavior. (Author abstract) 16 refs.

**080281 STRESS CORROSION CRACKING OF GLASS-FIBRE REINFORCED EPOXY RESINS.** Glass-fibre reinforced plastics with epoxy resin matrix (GF-EP) are known to respond with high sensitivity to a combined stress imposed by mechanical forces and mineral acids. This phenomenon is comparable with the stress corrosion cracking usually observed with metallic materials and is therefore also characterized as such in the case of GF-EP. In this paper the stress corrosion cracking of typical GF-EP insulators is determined quantitatively by fracture-mechanical experiments. From the obtained results material characteristic values are derived which can be used for the mechanical dimensioning of components and structural parts. A comparison of the material characteristic values of E- and ECR-glass fibre reinforced materials clearly exhibits the resistance of ECR glass fibres to media in composites. Thus, with respect to concentrated aqueous acids ECR glass-fibre reinforced materials exhibit a stress corrosion cracking sensitivity comparable to that of E-glass-fibre reinforced materials towards pure water. **080282 EFFECTS OF TEMPERATURE ON STRESS-RUPTURE TIMES IN GLASS/POLYESTER LAMINATES.** The stress-rupture times of glass fiber-reinforced plastics in water are temperature-dependent. Increasing the temperature increases the diffusion

coefficient of a liquid in a given matrix, and may also increase the fracture toughness of the resin. The effects of these two parameters on the rupture lifetimes oppose each other, and so the overall outcome could be either an increase or a decrease in failure time. This problem is illustrated by experiments with glass fiber-reinforced polyester laminates in water. The failure times were greater at 45°C than at either 60°C or 30°C. Acoustic emission experiments suggested that resin microcracking was extensive at 30°C but was much less at the higher temperatures, although the glass transition temperature was outside the experimental range. The sequence of events leading to failure is described. (Edited author abstract) 15 refs.

**080283 POISSON'S RATIOS IN GLASS FIBRE REINFORCED PLASTICS.** The characterisation of the mechanical properties of an orthotropic composite material generally requires nine interdependent elastic constants: three Young's moduli, three shear moduli and three Poisson's ratios. In most papers it is the practice to quote only two orthogonal axial moduli, a shear modulus and a Poisson's ratio in the plane of the laminate. However, the value of Poisson's ratio is a function of the orientation of the loading axis relative to the principal axis of the reinforcement fibres, both in and through the plane of the laminate. In an earlier paper, the correlation of experimental and theoretically predicted Poisson's ratios was reported around the angles in the plane of the laminate. Both unidirectional and woven roving fibreglass panels were tested. Accurate prediction of Poisson's ratio was shown to be critically dependent on the value of shear modulus used. **080285 PROPERTY MODIFICATION OF BULK MOLDING COMPOUNDS FOR USE IN INJECTION MOLDING.** Although impact and flexural strength of injection-molded bulk molding compounds increase initially with glass fiber content, these properties level out at a glass volume fraction between 0.1 and 0.2, limiting the achievable properties. Use of 'special purpose' polyester resins gives no significant improvement in impact. The impact strength limitation is not worsened, however, by using the maximum processable level of filler, this being true for all fillers commonly used in polyester compounds. Replacement of a fraction of the glass by poly(ethylene terephthalate) fibers results in a substantial improvement in impact strength. (Author abstract) 9 refs.

**080287 THERMAL EXPANSION OF POLYURETHANE REINFORCED WITH CONTINUOUS GLASS FIBERS.** This paper is concerned with the study of the thermal expansion properties of polyurethanes which are reinforced with randomly oriented continuous glass fibers. The thermal expansion of reinforced polymers is of prime importance since it has a significant effect on the overall dimensional stability of molded products. In this work the coefficient of linear thermal expansion (CLTE) is measured for both soft and rigid polyurethane containing various amounts of glass fibers. The experimental results show that: 1) there exists a maximum in the CLTE-temperature curves, the position of which depends on the type of resin and not on the glass content; 2) over the range of 0 to +70°C for rigid polyurethane, and -30 to +70°C for soft polyurethane, the CLTE decreases with temperature. The existence of a maximum in the above findings is confirmed with computations from a theoretical expression which was modified by the introduction of an efficiency factor. In applying this expression, parameters such as the Poisson's ratios, elastic moduli, and the CLTE's of the resins had to be evaluated at various temperatures. Based on these results, the CLTE-temperature curves were obtained and found to be in agreement with the experimental observations. (Author abstract) 12 refs.

**080289 WYTRZYMATOSC DORAZNA I ZMECZENIOWA POLIAMIDU WZMOCNIONEGO MIKROKULKAMI I WLOKNAMI SZKLANYMI.** [Immediate and Fatigue Strength of Polyamide Reinforced with Glass Microspheres and Fibers]. The immediate and fatigue strength of composites from polyamide-6 containing 58% by weight of glass reinforcement in the form of fibres and microspheres and differing in the relative amount of both reinforcements has been investigated. The exposure time in aging tests was from 1 to 24 months. It has been demonstrated that the addition of microspheres increases the fatigue strength and decreases the immediate strength of composites. A high value of the fatigue resistance coefficient for composites filled with microspheres only (much higher than the value of this coefficient for pure polymer matrix) justifies its potential applications in the construction of sliding blocks. **080291 SIMULATION OF LOW CYCLE FATIGUE FAILURE OF GLASS-MAT FRP BY AE METHOD.** Previously it has been shown that AE ring-down counts of glass-mat FRP in low-cycle fatigue loading become steady at the comparatively initial stage and their amounts are approximately linear with the fatigue life on a log-log diagram. In the present study, it was found that AE ring-down counts at each cycle during low-cycle fatigue could be evaluated from the strain response at the corresponding cycle by using the relation between strain and AE counts in static tests. It was also shown that the strain at each cycle during fatigue could be represented by the secant modulus and the modulus under unloading, and that both moduli at each cycle could be calculated from the applied stress and the secant modulus at the first cycle of the fatigue tests. Based on these concepts and then using the above-mentioned relation between AE counts and fatigue life, the prediction of low-cycle fatigue failure was made by a simulation method. A rather good agreement between the simulated and tested results was obtained. (Author abstract). 6 Refs. In Japanese.

**080292 RELATIONSHIP BETWEEN FRACTURE MECHANISMS AND AE CHARACTERISTICS OF MODEL GFRRP.** The fracture mechanisms of three kinds of model composites, such as the unidirectional glass fiber, the 0°/90° glass fiber and the plain weave cloth reinforced composites, were studied by using the acoustic emission (AE) method in tension, and by observation with optical and electron microscopes. It was found that the fracture mechanisms were different from each other because of their different types of reinforcement, and the AE event rate and the AE total energy were the effective parameters to make them clear. The fracture mechanisms could not be explained by the AE amplitude distribution, but by the power spectrum of AE waves based on the frequency analysis. The dominant frequencies in AE signals due to the matrix cracking, the debonding, the fiber breaking and the friction between fibers could be specified, and they increased in order of such phenomena. (Author abstract). 9 Refs. In Japanese.

**080293 FAILURE OF DUCTILE INTERLAYER COMPOSITES: HIGH-RESOLUTION X-RADIOGRAPHIC EXAMINATION USING AN OPAQUE PENETRANT.** The role of the interface between the components in any composite material is recognized as being of paramount importance in the determination of some properties, not least being the mechanical strength to failure. Generally this interface is the region in which bonding is achieved between the resin and the coupling agent on the fibres. The introduction of a ductile interlayer will alter the stress distribution in the regions around the fibres, thus delaying the transverse failure of the interface or resin which results in the premature weepage of pressure vessels or piping. In this study high-resolution

radiography has been utilized to study the failure of a glass fibre-epoxy composite and to examine the effects of the incorporation of a ductile interlayer. 8 Refs.

**080294 NEW APPROACH TO BULKED ROVING UPGRADES COMPOSITE PERFORMANCE.** A family of products designed to impart multiaxial reinforcement with uniaxial input has been created by a new approach to the manufacture of a bulked roving product. It is an outgrowth of Owens-Corning's spun roving programs in Europe, Canada, and the U.S. The new product distributes itself uniformly through a cavity over a wide range of glass contents. This allows it to fill a mold of variable cross-section - expanding and contracting within the available space to mold a solid section. It also can be made to have controlled axial extensibility ranging from high (for performing) to low (for pultrusion and filament winding). This paper outlines the process used to form the product, discusses the format and concept of the product, defines selected performance aspects, and presents property data comparing the bulked roving systems to existing products such as Fiberglas Canada 852 HC 4035 spun roving and OCF 424BA Type 30 roving. Information on the performance of Type 30 bulked roving hybrids is also presented.

**080295 WET-LAID PROCESS FOR THE PREPARATION OF RANDOM FIBER-REINFORCED COMPOSITES.** There are several proven methods of preparing fiber-reinforced plastics (FRP). Each of these methods has some limitations. Dow's Random Fiber Composite (RFC) process was developed to reduce the disadvantages of the slow and inefficient methods of composite-sheet or hand lay-up fabrication. The benefits of the wet-laid process, such as maximum fiber debundling during processing, minimum degradation, and complete randomization of the short fiber, as well as successful results of laboratory tests are described. Typical physical processes of glass-reinforced HDPE and polypropylene composites prepared in the laboratory are given. The process was tested on a pilot-sized fourdrinier continuous paper machine. Several advantages of the RFC process are worked out and some products, such as the EMI (electromagnetic interference) shielding composites and electrical circuit board composites, are described.

**080296 MECHANICAL PROPERTIES OF FRP WITH BRAIDED STRUCTURE PART 3: BENDING BEHAVIORS OF TUBES.** Tubes with four kinds of braiding angles were fabricated. The test method was four-point bending type. The deformation state and the stress distribution of the specimen under bending load were checked by using the finite element method. The main results are: in the case of the specimen with low braiding angle, the fracture was initiated in the compression side of the tube and then the buckling failure occurred, but the tension failure occurred in the case of the high braiding angle; the bending modulus and the bending strength of the tube were increased with decrease of the braiding angle; the through-the-thickness braided tubes could improve the bending modulus in all types of tubes. (Edited author abstract). 11 Refs. In Japanese.

**080297 PREFORMS PAVE THE WAY FOR LOWER-COST STRUCTURALS.** After several decades in the shadows, fiber glass preforms are once again becoming a factor in reinforced plastics. The action in structural parts is mostly in automotive, but once the technology is developed, similar applications will start to emerge in recreational and agricultural vehicles, industrial

equipment, and large appliances. With the advent of highspeed reactive polymers that produce Class A surfaces, moreover, these two low-pressure processes may edge into production volumes that have traditionally been SMC's turf. The combination of faster chemistry, new low-profile polymers, plus the growing demand for parts for low-volume niche vehicles, will begin pulling molders of conventional RIM parts into the arena structurals and semi-structurals.

**080298 WELDLINE INTEGRITY OF REINFORCED PLASTICS: EFFECT OF FILLER SHAPE.** The paper is a preliminary report on glass fiber and glass flake orientation in the weldline zone of injection molded reinforced polypropylene. Two types of weldlines were studied using simple shape molds: one where two melt streams meet head-on and become immobilized, the other where the weldline formation is followed by additional flow. In the weldlines of the first type, which are characteristics of current standard molds used to test weldline strength, the anisometric particles are almost perfectly oriented perpendicular to flow. As a result, the weldlines of this type tend to be weak and brittle. In the second case when the weldline is formed by merging of melt streams separated by an insert, particle orientation in the weldline area remains different from other areas of the sample for long distances from the insert. It is shown that in molds where the weldline formation is followed by laterally expanding flow the change of particle orientation is faster than for unidirectional flow. (Author abstract) 21 refs.

## Glass Transition

**080299 BESTIMMEN DES GLASUEBERGANGS VON FASERVERBUNDWERKSTOFFEN IM STATISCHEN ZUGVERSUCH.** [Determination of Glass Transitions in Fibre-Reinforced Materials by a Static Tensile Test]. The maximum service temperature for fibre-reinforced materials with organic matrices is usually limited by the softening of the matrix as it approaches its glass-transition region. This can be determined approximately by a thermomechanical test. Since moisture content and rate and severity of loading affect the position of the glass transition, the test must be carried out as far as possible under conditions that lead, in practical use, to the lowest glass-transition temperature. For  $\pm 45^\circ$  laminates these conditions can best be simulated by a static tensile test, rather than by the use of the normal torsion pendulum test and dynamic mechanical analysis. (Author abstract) 10 refs. In German.

**080300 ADHESION AT THE INTERFACE IN CURED GRAPHITE FIBER EPOXY-AMINE RESIN COMPOSITES.** The effect of high temperature curing on the interface between unsized or epoxy-sized graphite fiber tow and epoxy-amine resin was examined by scanning electron microscopy of compression and freeze fractured specimens. Little or no adhesion was found between the unsized graphite fiber tows and the epoxy-amine resin on curing at 165°C for 17 hrs. Epoxy-sized graphite fibers showed a similar lack of adhesion between the fiber tows and the epoxy-amine resin at 3 and 17 hrs. cures, although good penetration of the resin into the sized fiber tows had

occurred. Interfacial bond strengths for the composites could not be effectively measured by compression fracture of specimens. (Author abstract) 10 refs.

**080301 GRAPHITE AS AN IMBEDDED STRAIN GAUGE MATERIAL.** Graphite epoxy composite material offers a unique window into its state of strain or structural integrity. Since unidirectional graphite epoxy composites possess an electrical resistance in the direction of the fibers over four orders of magnitude less than the electrical resistance across the fibers, electrical resistance measurements can be accurately correlated with strain in the fibers. Moreover in the case of internal damage in which the graphite fibers are broken, the electrical resistance measurements can serve as a clear indicator of internal damage which might not be otherwise apparent. The actual values of strain sensitivity,  $S_A$ , as calculated from the resistance measurements, varied between 1.2 and 1.8. These values depended critically upon the exact geometry of each hand laid up specimen, and with more control over the specimens in the future, a more accurate value for  $S_A$  for this material can be expected. However, for a single, typical specimen, the apparent value of  $S_A$  stayed constant to within  $\pm 4\%$  over a wide range of strain, indicating that with calibration the graphite can serve as its own strain gauge with the same accuracy. **080304 SPACE STRUCTURES...BUILT IN SPACE.** On-orbit manufacture of large space structures could be closer to reality as the result of the development of high-temperature, high-strength thermoplastic polymers. These high-performance thermoplastics, when used as matrices with high-modulus graphite fibers, produce structures that are 35 to 40 percent lighter and two to five times stronger than conventional aluminum alloys. With the technology firmly in place, there is every practical reason that polyetherimide and polyetheretherketone composites can be cost-effectively orbit-pultruded into channels, hat sections, and I-beams to construct large space dwellings and other components. Use of coiled stock pultruded on earth can result in substantial decrease in

payload volume (and hence shuttle weight) for earth-to-orbit transport. 8 Refs.

**080305 USE OF WEIBULL STATISTICS TO QUANTIFY SPECIMEN SIZE EFFECTS IN FATIGUE OF GRP.** Data are presented to show that changing specimen size has a considerable effect on the fatigue life of unidirectional GRP. As the volume of material under stress is increased, the probability of the existence of a severe defect also increases and so the expected fatigue life will decrease. Weibull statistics are used to calculate the magnitude of this effect, and the predictions tested against the experimental data. Within the limits of its accuracy, the model was found to account for the observed differences in the fatigue lives of specimens and large sections cut from components, in most situations. The Weibull predictions are tested against experimental data obtained for unidirectional glass reinforced epoxy composites tested in flexure. (Edited author abstract) 8 refs.

#### Injection Molding

**080306 SOME FEATURES OF THE INJECTION MOLDING OF SHORT FIBER REINFORCED THERMOPLASTICS IN CENTER SPRUE-GATED CAVITIES.** This paper describes an investigation into the fiber orientation in a number of center sprue fed cavities in short glass fiber filled polypropylene and nylon. The data have been interpreted in terms of a generalized five-layer structure resulting from the frozen skin formation and the high and low shear levels in the flowing melt. The implications for scaling up the mold size are discussed from the results obtained with different short volumes. The fiber structure was observed to depend on location in the molding, local injection time, and injection rate. In addition the occurrence of fiber-free layers within the moldings using the filled polypropylene increases with an increase in short volume, which produces an inherent 'scale-up' problem. Notwithstanding the mold geometry subtleties, the fiber orientation in all the moldings follows similar patterns and trends. (Author abstract) 20 refs.

**080307 MOLD-FILLING SIMULATIONS FOR THE INJECTION MOLDING OF CONTINUOUS FIBER-REINFORCED POLYMER.** Injection molding can be used to fabricate fiber-reinforced polymer composites by impregnating a continuous fabric mat preplaced in a mold cavity with a polymer resin. The mold-filling time is dependent on the flow and heat transfer behavior in the mold. A model is proposed that considers the non-Newtonian flow through the porous fabric mat and the heat transfer between mold, fabric mat, and flowing fluid. The model was simulated for the mold filling of a carbon fiber mat with a pseudoplastic polymer solution. The results from the simulation provide information for optimizing mold-filling parameters through proper selection of inlet fluid pressure, heat source temperature, and type of polymer-solvent system. (Author abstract) 12 refs.

**080308 SPRITZGIESSEN VON KOHLENSTOFFASERVERSTAERKTEM POLYCARBONAT.** [Injection Molding of Carbon-Fiber-Reinforced Polycarbon-

ate]. In order for fiber reinforcements in thermoplastics to be as effective as possible, the fibers must be firmly bonded to the matrix resin and fiber length should be as long as possible. Using carbon fibers that were specially treated to promote adhesion to polycarbonate, an investigation was conducted to determine the physical properties attainable when the fiber-matrix mixture is processed directly in an injection molding machine. It was found that higher values for tensile and flexural strength were attained in comparison with a commercially available, compounded material. (Author abstract) 2 refs. In German.

#### Inspection

**080309 ESTABLISHING CRITERIA FOR A COMPUTERIZED VISION INSPECTION OF HOLES DRILLED IN CARBON FIBER COMPOSITES.** Two basically different carbide bit designs, a dragger bit and a standard twist drill, were tested extensively in graphite/epoxy composite material. A commercially available computer vision system was utilized to evaluate hole quality as the bits wore from fraying, delamination, and hole tolerance. Methods and procedures for establishing acceptance criteria using the vision system are given. Based on manual acceptance criteria, vision system criteria were established for fraying and suggested for entrance delamination. (Author abstract) 8 refs.

#### Laminating

**080310 THERMOANALYTICAL INVESTIGATION OF COMPOSITE LAMINATION.** Glass cloth reinforced epoxy resins are commonly used to make composites. The performance of these laminates depends strongly on optimizing cure kinetics and rheology for a given chemical composition and temperature/pressure profile. Aborted flow tests (weight percent resin squeezed out during a given temperature/pressure cycle) is frequently used to emulate lamination process and/or to evaluate new formulations. The cure reaction was monitored using different scanning calorimetry, rheology, and dielectrometry. Gravimetric and thickness measurement indicated a non-uniform resin distribution across the laminate, with a lower resin content found at the edges. Macroscopic flow is controlled by three dimensional heat transfer, which leads to a dynamic temperature distribution and, concomitantly, to a cure/rheology profile. (Edited author abstract) 18 refs.

#### Machining

 See Also CUTTING TOOLS—Diamond.

**080311 BEARBEITUNG FASERVERSTAERKTER KUNSTSTOFFE MIT WASSER- UND LASERSTRAHL.** [Machining of Fiber-Reinforced Plastics by Means of Water Jet and Laser Beam]. The specific advantages of water jet cutting have opened up a broad field of application in machining fiber reinforced plastics. The requirements for high cutting rates without damaging the workpiece restricts the application of this technology to thin walled components. A clear improvement of the working results both on qualitative level and by shifting the limits of performance toward a higher material thickness can be achieved by adding solids to the water jet. Whereas trimming of fiber-reinforced plastics by means of the water jet has become an industrially well known method, laser beam cutting has not been introduced that widely. Reduction of the thermal damage produced by this method and the roughness of the cut surfaces can be achieved by the appropriate process parameters but also by the application of lasers of shorter wavelengths. (Edited author abstract) In German. 6 refs.

**080314 THERMAL STRESSES IN ROD COMPONENTS MADE OF COMPOSITES PRODUCED BY THE SPIRAL WINDING METHOD.** In producing components based on high-modulus hybrid fillers, their mechanical and service characteristics are increased and processing properties improved by introducing a layer of a reinforcing fiber placed along a spiral around the main reinforcing material. Additional stresses and strains caused by the interaction between the rod element and the winding layer with temperature variations may appear in the structure of the composite. We examine thermal deformation of an element of a rod with the length equal to the winding step  $t$ . The results of the investigations show that it is possible to control in the required direction the magnitude of the thermal stresses and strains in the rod elements and composites with spirally reinforced fillers by the rational selection of the materials of winding layers, their geometrical dimensions, and laying angles. 6 refs.

**080315 EFFECT OF GLASS FIBER LENGTH ON THE CREEP AND IMPACT RESISTANCE OF REINFORCED THERMOPLASTICS.** Impact and flexural creep testing were conducted at temperatures between  $-22^{\circ}\text{F}$  ( $-30^{\circ}\text{C}$ ) and  $250^{\circ}\text{F}$  ( $121^{\circ}\text{C}$ ) to evaluate and compare the end-use performance of continuous long glass fiber-reinforced thermoplastic sheet composites to that of short glass fiber-reinforced thermoplastics. The matrices studied consisted of amorphous (polycarbonate and acrylonitrile-butadiene-styrene) and semicrystalline (polypropylene) polymers. Data were obtained from both injection-molded specimens (short fibers), and from specimens machine-cut from compression-molded test panels (continuous long fibers). The results of this study point to the significant property improvement of continuous long fibers vs. short fibers. (Edited author abstract) 38 refs.

**080316 ULTRASONIC EVALUATION OF FILLED POLYMERS. II. ELASTIC MODULI OF A RESIN FILLED WITH IRON INCLUSIONS OF DIFFERENT ASPECT RATIOS.** An ultrasonic technique is used for the nondestructive evaluation of elastic moduli of polymer composites. Samples with varying amounts of randomly oriented iron inclusions, having aspect ratios  $p=0.20$  (flakes) and  $p=20.0$  (short fibers), were fabricated and fully characterized. The results for the moduli are discussed in terms of available theoretical models. It is demonstrated that models which account for the microscopic details of the material offer a good description of the bulk properties. Also, experimental evidence is obtained for the effect of particle contiguity and allows one to evaluate the influence of particle/particle interaction. (Author abstract) 20 refs.

**080317 FATIGUE STRENGTH OF AROMATIC POLYAMIDEIMIDE-AROMATIC POLYAMIDE FIBER COMPOSITE FILMS.** For the purpose of making a more flexible composite, an aromatic polyamideimide (PAI) film was reinforced by aromatic polyamide fiber (Du Pont, Kevlar 49) to form a bidirectionally oriented cloth composite. The fatigue strength of this composite film was investigated by cyclic tensile stress, with respect to the direction of fiber orientation. In the cloth composite film, the fatigue behavior was anisotropic, as were the other mechanical properties. The characteristics of fatigue life at the composite film were related to the intermediate characteristics of fatigue life at both the cloth reinforcement and the PAI matrix. The fatigue strength of the composite film may be correlated with its static strength. (Author abstract) 9 refs. In Japanese.

**080318 EFFECTS OF WELD LINE ON STRENGTH OF FIBER REINFORCED THERMOPLASTICS INJECTION MOLDING.** The strength of fiber reinforced thermoplastics (FRTP) injection molded parts is reduced by weld lines. The aim of this study is to clarify the mechanism of weld lines and the effects on strength of molding. The materials used are fiber reinforced polycarbonate (PC) with 10, 20, and 40 wt% glass fiber content. Dumbbell-shaped tensile test specimens with weld lines were molded at various injection pressures, cavity pressure, and resin temperature were noted. Measurement of tensile strength and observation of the weld region were carried out. The ratio of strength with weld line to that without weld line decreases remarkably with increasing fiber content. The strength of the molding with weld line increases with the filling pressure and/or the holding pressure. (Edited author abstract) 10 refs. In Japanese.

**080319 TENSION AND COMPRESSION OF GLASS REINFORCED AND ORGANIC PLASTICS AT ROOM AND CRYOGENIC TEMPERATURES.** The work described in this paper is the continuation of the systematic investigations by the authors of the behavior of organic plastics in comparison with glass reinforced plastics with the same arrangement of the reinforcement, the same loading conditions, at the same temperatures. The investigations were confined to the class of wound materials with a crossed structure based on epoxy binders. The experiments were carried out at room temperature at cryogenic and elevated temperatures. The present work entailed the study of the strength, elastic, and deformation characteristics of glass reinforced and organic plastics under tension and compression at 293 and 77°K. 17 refs.

**080320 EFFECT OF TREATMENT OF COUPLING AGENTS ON DYNAMIC MECHANICAL PROPERTIES OF GLASS FLAKES-FILLED EPOXY RESIN.** The affinity between glass flakes (GF) treated with silane, titanate, and phosphate coupling agent (SCA, TCA, and PCA) and epoxy resin cured with hexahydrophthalic anhydride and 4,4'-diaminodiphenylmethane was studied by dynamic modulus, compressive strength, and SEM measurements. The volume fractions of GF in the composite materials were 0.49 to approximately 0.61. SEM photographs of cut edgewise surface of the filled samples show that GF particles untreated and treated with coupling agents are aligned as a layer. Dynamic mechanical properties of the specimens were measured over the temperature range from room temperature to about 250°C. (Edited author abstract) In Japanese. 29 refs.

**080321 EFFECTS OF FIBER LENGTH AND ORIENTATION DISTRIBUTION ON THE ELASTIC MODULUS OF SHORT FIBER REINFORCED THERMOPLASTICS.** A method including the effects of fiber length and orientation distribution to predict elastic moduli of short fiber reinforced thermoplastics (FRTP) is presented. The fiber length distribution in FRTP has an asymmetric character with a tail at the long fiber end. Statistical distribution functions such as Weibull or log-normal can be used to represent this kind of distribution. Orientation distribution of fibers in FRTP can be characterized by a single parameter exponential function. The mean elastic moduli of unidirectional plies are predicted through the fiber length distribution. Then the stacking sequence of laminate is assumed to be as the fiber orientation distribution of FRTP, and the overall elastic moduli of FRTP are estimated based on the laminate-plate method. (Edited author abstract) 15 refs.

**080322 DAMAGE SUSTAINED BY A CARBON/EPOXY COMPOSITE MATERIAL SUBJECTED TO REPEATED IMPACT.** The damage sustained by 16-ply quasi-isotropic carbon/epoxy composite laminates subjected to repeated impact at various energy levels has been quantified. Composite plates 2 mm thick were fabricated using Hercules AS4/3501-6 carbon/epoxy unidirectional prepreg. Impact energy level and number of impacts were found to be major factors influencing damage. However, damage was limited to the region near the impact point. Several damage assessment techniques were evaluated and subsequently used. (Author abstract) 9 refs.

**080323 PHYSICAL ADHESIVE FACTOR BETWEEN POLYMER AND FILLER WHICH AFFECTS TENSILE STRENGTH OF FIBER REINFORCED COMPOSITE MATERIALS.** The effects of shrinkage in injection molding on the tensile strength of fiber reinforced composite plastics have been investigated. Tetrafluoroethylene copolymer (ETFE) and polyethylene (PE) etc. were reinforced by glass fibers, and polyamide (PA12) and polyethylene (PE) were reinforced with glass fibers and aramid fibers, respectively. The ratio of tensile strength of fiber reinforced composite materials to that of matrix polymer tends to become higher with increasing mold shrinkage in spite of the small adhesion difference between filler and polymer. The physical adhesion of the matrix materials to fibers is improved with increasing mold shrinkage of base polymer. These results show that

the mold shrinkage is one of the factors which affect the tensile strength of filler reinforced injection moldings. (Edited author abstract) In Japanese. 11 refs.

**080324 INFLUENCE OF WATER ON TENSILE AND FATIGUE PROPERTIES OF TWO TYPES OF ARAMID/EPOXY COMPOSITES.** An investigation has been carried out concerning the effect of water absorption on the tensile and fatigue properties of a Technora (HM50, Teijin)/epoxy and a Kevlar49 (DuPont)/epoxy composites. The effect of water on the fracture mechanism was observed using AE measurements and SEM microscopy. The weight gain for the HM50 specimens immersed in distilled water at 70°C levels off at about 2% after two months. For the Kevlar49 this is about 3.5%. Moisture does not appear to have any influence on the tensile strength. For the HM50 the elastic moduli of the dry and wet specimens are the same at the start. After a certain point the dry specimen stiffens, whereas the wet one first yields, and then stiffens. The Kevlar49 specimens do not show any yielding behavior unlike the HM50. For both composites the specimens in water exhibit a longer fatigue life than in air, though the Kevlar49 has a slightly bigger increase in life than the HM50. Additional study results are discussed. **080325 EFFECT OF MODIFICATION WITH LIQUID CARBOXYL TERMINATED NITRILE RUBBER ON PEEL STRENGTH OF CARBON FIBER/TETRAFUNCTIONAL EPOXY RESIN COMPOSITE.** With tetrafunctional epoxy resin (tetraglycidyl-4,4'-diaminodiphenylmethane) used as a matrix resin, the effect of modification with liquid carboxyl terminated nitrile rubber (CTBN) on the peel strength of carbon fiber composite was investigated. The peel strength increased with increasing CTBN content. The strengths became higher with lower measuring temperature or higher peel rate, and superposed as a function of temperature or peel rate. The observation of fracture surfaces after peel test with a scanning electron microscope (SEM) revealed that, in the region of low temperature or high peel rate, there were numerous CTBN particles of 2-20 µm diameter and numerous holes, produced by pulling out these particles from epoxy resin. (Edited author abstract) In Japanese. 15 refs.

**080326 HIGH IMPACT PROPERTIES OF THERMOPLASTIC RESIN-METAL SYSTEM.** High impact resistant properties of various thermoplastic resin-metal systems were investigated. A high speed piercing test successfully simulates the fracture pattern caused by shotgun shooting. Though the thermoplastic styrene elastomer has the highest fracture energy, this energy is noticeably reduced when it is laminated with stainless steel. In this system the elongation of the thermoplastic styrene elastomer, which governs the impact-absorbing ability, is restrained by the stainless steel. Vinyl chloride-ethylene vinyl acetate graft copolymer, which has the highest fracture stress, exhibits the best impact resistant properties. (Edited author abstract) In Japanese. 7 refs.

**080327 SURFACE TREATMENT OF FILLERS FOR POLYMER COMPOSITES.** The effects of surface treatment of E-glass particulate fillers and the mechanical properties of acrylic polymer composites containing the fillers have been studied. The coupling agents used were cyclohexyl trichlorosilane (CS) with strong hydrophobic group and  $\gamma$ -methacryloxy propyl trimethoxysilane ( $\gamma$ -MPS). The existence of coupling agents on the filler

surfaces was confirmed by the absorption bands of difference FT-IR diffuse reflectance spectrum. Tensile and compressive strengths of the composites were improved by the  $\gamma$ -MPS treatment of the fillers, but not by the CS treatment. (Edited author abstract) In Japanese. 7 refs.

**080328 DESIGN IMPLICATIONS OF STIFFNESS AND THICKNESS.** Plastics reinforced with short fibres often show fibre alignment effects, which are normally introduced unintentionally during processing. An increase in thickness modifies the flow pattern during mould filling, alters the distribution of fibre orientation across the thickness of the part and reduces the effective flexural modulus of the moulding. DuPont scientists and technologists have carried out a pilot study covering glass and carbon fibres that improves understanding of the variation of flexural modulus with thickness. The information about thickness-dependent changes in the anisotropy of mechanical properties can be used in modified design formulae. 1 ref.

**080329 EXCELLENT FLEXURAL PROPERTIES OF AMINIMIDE-CURED EPOXY RESIN AS A MATRIX FOR MICA-DISPERSED POLYMER COMPOSITES.** The flexural strength and flexural modulus have been determined as a function of the volume fraction of mica flakes for both aminimide-cured epoxy resin matrix and a conventional epoxy resin reference matrix. On the basis of microscopic observation of fractured surfaces, the effect of improving the particle-matrix interface has been analyzed using the modulus reduction factor in a modified form. There is a steady increase in the flexural modulus with the volume fraction of mica flake for the aminimide-cured epoxy resin matrix. In contrast, the increase in flexural modulus levels off at a high content of filler for the reference samples. The intact mica flakes without surface treatment exhibit a reinforcing effect on the flexural strength in the aminimide-cured epoxy resin composites. The reference epoxy resins behave like conventional matrix resins, exhibiting 30 to 40% reduction in the flexural strength when a small fraction of mica is added. These superior properties of the matrix resin are ascribed to the characteristics of aminimide-cured epoxy resins such as hardness, toughness and adhesivity. (Edited author abstract) 14 refs.

**080331 IMPACT PERFORMANCE OF SISAL-POLYESTER COMPOSITES.** In a previous letter it was reported that a sisal fiber composite exhibits maximum impact toughness owing to the optimum microfibrillar angle of the fiber. In the course of the present study an investigation on the impact properties of sisal composite (unidirectional system) was carried out. The sisal composite shows work of fracture identical with that of an ultra high modulus polyethylene (UHMPE) composite and the toughness is only 25 percent less than that of glass fiber composite when the density of the latter is taken into account. Although the impact performance of the sisal

composite is attractive, other mechanical properties are inferior to those of synthetic fiber composites. 4 Refs.

**080333 DYNAMIC MECHANICAL ANALYSIS STUDIES OF THE INTERPHASE.** The dynamic mechanical properties of unidirectional glass-fiber-reinforced polyester measured along the fiber direction were recently investigated. In the same polyester, the type of organosilane coated on the glass fiber, the amount of organosilane, the fiber volume fraction, and the fiber diameter affect the value of the loss tangent,  $\tan \delta$ , at the glass-transition temperature of the glass-fiber-reinforced polyester. The interfacial shear strength and the  $\tan \delta$  at the glass-transition temperature of the glass-fiber-reinforced polyester show good correlation suggesting that the latter can be used to characterize the quality of the interphase. Factors affecting the glass-transition temperature and the application of Zorowski and Murayama's equation in the characterization of the interfacial adhesion are also discussed. (Author abstract) 11 refs.

## Microstructure

**080336 MICROSTRUCTURE AND FRACTURE TOUGHNESS OF SHORT FIBRE REINFORCED INJECTION-MOULDED PEEK COMPOSITES.** The fracture toughness ( $K_Q$ ) of injection-molded polyetheretherketone (PEEK) composites containing 20 and 30% glass and 30% carbon fibers, respectively, was evaluated using compact tension specimens.  $K_Q$  is regarded as a function of the microstructural efficiency factor ( $M$ ) which takes into account the anisotropic fiber orientation and layered structure caused by injection molding. Failure mechanisms for both the non-reinforced and reinforced PEEK were characterized by fractography in a scanning electron microscope. It was shown that in the knowledge of  $M$  and its additive terms, i.e. matrix stress conditions factor and energy absorption coefficient, the fracture and failure behavior of the composites can be predicted. The results are summarized in the form of failure and fracture maps. (Edited author abstract) 23 refs.

**080337 WATER ABSORPTION OF RESINS AND COMPOSITES. IV. WATER TRANSPORT IN FIBER REINFORCED PLASTICS.** An analysis of diffusivity of composites is described in which an electrical resistance analogy is used. This leads to an expression for diffusivity, which takes into account the contribution of fiber diffusivity, matrix diffusivity, and the diffusivity of the interphase, when this is different from that of the polymer matrix. The case involving the interphase requires numerical integration for its solution. However, the effect of the interphase can be very accurately simulated in a more approximate model; a closed form expression for composite diffusivity is obtained that agrees with the numerical analysis within better than 1% if an appropriate adjustment for interphase width is made. The same approach was used for including voids in the analysis, and it is shown that, in some experiments described previously with glass and carbon fiber pultrusions, the results can be explained on the basis of the voids in the composite providing an enhanced diffusion path for water. (Edited author abstract) 10 refs.

**080338 OUT OF THE BAG.** Vacuum bag molding offers many advantages for the shaping of composite components. The composite material is laid on a single mold tool and then covered with a flexible membrane. The membrane is sealed onto the tool and the area under the bag evacuated. This causes the membrane to collapse and impart a uniform downward pressure on the composite molding. The next stage is to move the whole mold assembly into a large oven for heat curing of the resin. This article discusses these and describes the steps needed to apply the technique successfully.

**080339 MODEL FOR RESIN FLOW DURING COMPOSITE PROCESSING. PART 2: NUMERICAL ANALYSIS FOR UNIDIRECTIONAL GRAPHITE/EPOXY LAMINATES.** In this paper numerical

results are presented for resin flow during processing of unidirectional graphite/epoxy laminates. Resin pressure and velocity profiles, as well as resin loss, specific permeability, and resulting thickness changes, were computed to examine the effects of one- and two-dimensional flow, initial laminate thickness, and various curve cycles. Input data to the model are also discussed in detail. Analysis of the input data on the stress-strain behavior of graphite fiber beds showed that the bed consolidation behavior can be divided into three regions. Comparison of the predicted results for the resin mass loss and the average final thickness per ply with experimentally determined values shows good agreement. (Edited author abstract) 23 refs.

**080340 MODEL FOR RESIN FLOW DURING COMPOSITE PROCESSING. PART 1. GENERAL MATHEMATICAL DEVELOPMENT.** A generalized three-dimensional model for resin flow during composite processing has been developed. The model is based on a theory of consolidation and flow through a porous medium, which considers that the total force acting on a porous medium is countered by the sum of the opposing forces, including the force due to the spring-like effect of the fiber network and the hydrostatic force due to the pressure of the liquid within the porous medium. The flow in the laminate is described in terms of Darcy's Law for flow in a porous medium, which requires a knowledge of the fiber network permeability and the viscosity of the flowing fluid. Unlike previous resin flow models, this model properly considers the flows in different directions to be coupled and provides a unified approach in arriving at the solution. (Edited author abstract) 40 refs.

**080342 DIFFERENTIAL SCANNING CALORIMETRIC DETERMINATION OF THE VOLATILE CONTENT AND PROPERTIES OF EPOXY PREPREG.** Differential scanning calorimetry (DSC) is widely used to determine the B-time reduction, curing rate and state of cure of prepregs. The object of the work was to investigate whether the prepreg volatile content could be determined with DSC and to ascertain whether changes in the volatile content caused any changes in the prepreg processing characteristics through any effect it may have on the glass transition temperature. The Diverrit ML prepregs (Dielektra Grade no., 15193/106) used consisted of a thin glass fabric impregnated with epoxy polymer advanced to B-state (semicure). The prepregs which have lower volatile content and lower  $T_g$  have higher compressibility and flowability and lower viscosity during laminating. DSC can also be used to determine the volatile content. The processing, but not the curing characteristics are influenced by volatile content. 4 Refs.

## Protective Coatings

**080343 AIRCRAFT CONSTRUCTION: PROTECTIVE COATINGS FOR FIBRE-REINFORCED PLASTICS.** Elastomeric coatings can reduce mechanical damage caused by composites, which are rigid materials, exhibiting internal fibre breakage under hard impact during fabrication or use. The resins used in construction

are not selected for optimum erosion-resistance, but tough protective coatings can allow the use of these materials in high erosion areas. Elastomeric primers, even when used under traditional coatings, improve erosion-resistance.

Morris, Lester (Aircraft Coatings Research & Development Lab, Burbank, CA, USA); Randazzo, Santo. *Aircr Eng* v 60 n 4 Apr 1988 p 22-23.

## Pultrusion

**080344 PULTRUDED COMPOSITES: THE ALTERNATIVE STRUCTURAL MATERIAL.** Pultrusion is an extremely efficient technique for producing composite components in linear form. At present the European market for pultruded profiles is growing at a rate of 20% per annum and defence applications account for an important proportion of this, especially in the area of carbon fiber reinforced epoxy resin. The composite equivalent of extrusion, pultrusion produces profiles which are similar in the range and complexity of shapes achievable, but are structural by nature, that is, capable of load bearing.

Anon. *Eng Mater Des* v 31 n 10 Oct 1987 p 54,57.

**080345 JUST HOW BIG IS PULTRUSION'S FUTURE IN STRUCTURAL COMPONENTS.** No longer limited to aerospace components and premium sporting goods, pultrusion has evolved into a major process that consumed more than 110 million lb. of resins and reinforcements last year, according to the Composites Institute of the Society of the Plastics Industry. This trade group predicts 12 to 15 percent growth this year, as applications expand beyond driveshafts, structural shapes, and exterior/interior bus panels. Indications abound, not least of them commercial acceptance in window profiles and as I-beams in high-rise building. Process and material refinements continue to expand marketing horizons.

Wilder, Robert V. *Mod Plast* v 65 n 7 Jul 1988 p 37-39.

**080346 NOVEL REINFORCED REACTION INJECTION MOLDING (RRIM) PROCESSING: COMPUTER-CONTROLLED MULTIPLE-STREAM RRIM PRODUCTION OF INTERPENETRATING POLYMER NETWORK AND POLYURETHANES.** A four-stream computer-controlled reinforced reaction injection molding (RRIM) machine has been developed that attains high accuracy in dispense ratios throughout the injection process. This machine has been used for novel processing of polyurethanes, offering a route to varying product properties either throughout a shot or a shot-to-shot basis. It also has been used for what appears to be the first production on commercial scale RRIM equipment of a polyurethane-acrylic interpenetrating polymer network (IPN) in commercial cycle times of around 2 min. (Author abstract) 17 refs.

Coates, P.D. (Univ of Bradford, Engl); Johnson, A.F.; Armitage, P.D.; Hynds, J.; Leadbitter, J. *Polym Eng Sci* v 27 n 16 Mid-Sep 1987 p 1209-1215.

**080347 HIGH-STRENGTH STRUCTURAL COMPOSITES MADE BY RIM.** A reinforced resin system that combines reinforced injection molding (RIM) and resin transfer molding is an economical route to the manufacture of large high-strength automotive parts. Optimum reinforcement is achieved by precise placement of reinforcement in molds. Glass mat is most popular, but other media, such as carbon and aramid fiber, may be used.

Nelson, Don (Dow Chemical Co, North Haven, CT, USA). *Plast Eng* v 43 n 11 Nov 1987 p 29-32.

**080348 MICA AS A REINFORCEMENT FOR POLYURETHANE RIM.** Polyurethane reaction injection molding (RIM) systems are reinforced with inorganic materials to improve stiffness and structural integrity at elevated temperatures and to reduce the coefficient of thermal expansion. This work describes the reinforcement obtained with an experimental grade of mica designed to achieve low viscosity in polyol mica suspensions. The effect of mica on properties is essentially identical to that of glass flake. Compared to hammer milled glass, mica and glass flakes yield more isotropic, albeit weaker, materials. (Edited author abstract) 15 refs.

Naik, Saurabh (Marietta Resources Int, Hunt Valley, MD, USA); Fissa, B. *J Reinf Plast Compos* v 6 n 4 Oct 1987 p 319-330.

**080349 MOLDING BY REACTIVE INJECTION OF REINFORCED PLASTICS.** A model for the molding by reactive injection of reinforced plastics for systems in which fiber glass reinforcements are placed into the molds, is proposed. It allows for the determination of processing parameters and their influence on dependent variables: conversion, temperature, and pressure. Moldability areas, where premature gelling is avoided, are defined. Operating conditions are selected to reduce cycle time, produce small load losses, and provide a fairly uniform curing stage throughout the product. (Author abstract) 9 refs.

## Reactive Molding

**080350 SYSTEM DEVELOPED FOR MOLDING LARGE, COMPLEX AUTOMOTIVE PARTS OF POLYMER COMPOSITE.** A new low-viscosity, glass mat-reinforced polyurethane structural foam system for automotive parts has been developed. In testing at Mobay Laboratories, the material increased productivity as much as 40% for the manufacture of automotive interior trim panels. Able to be processed by economical closed-mold reaction injection molding (RIM), the new material can also help reduce the thickness and weight of automotive parts currently made from wood fiber and plastic laminates. These improvements are made possible while maintaining the excellent physical properties of structural foam. It is possible to produce beams with the new composite system that have a stiffness approaching that of steel counterparts, but weigh considerably less.

Anon. *Ind Heat* v 54 n 12 Dec 1987 p 30-31.

## Reviews

**080351 ADVANCED POLYMER COMPOSITES: AN INTERNATIONAL PERSPECTIVE.** Due to their desirable performance properties, advanced polymer composites will continue to grow and penetrate new markets over the next ten years. This creates opportunities within each segment of the industry: resins, fibres, fabrics, prepreps and shapes. A supplier's success requires a commitment to research and application development, investment in appropriate resources and the patience to endure both long application development and approval time in certain market segments. Despite these factors, the rewards can be substantial. (Author abstract)

## Strain

**080352 SHEAR STRAINS IN A GRAPHITE/PEEK BEAM BY MOIRE INTERFEROMETRY WITH CARRIER FRINGES.** A multispan quasi-isotropic graphite-PEEK beam exhibited dramatic shear strains in the interlaminar region between plies. Shear strains in the

plies themselves varied in basic accord with fiber direction. The large anomalous shear strains were developed near the center of the beam height, where shear stresses were large. High-sensitivity moire interferometry with 2400  $\ell/\text{mm}$  (60,960  $\ell/\text{in.}$ ) was used. A new technique of data extraction was developed, using carrier fringes to transform the pattern to one in which fringe slopes are proportional to derivatives of displacement. This technique enhanced detection and measurement of highly localized shear-strain gradients. (Author abstract) 3 refs.

**Structural Application** See Also AUTOMOBILE MATERIALS—Plastics.

**080354 PULTRUDED STRUCTURES WIN SUPPORT.** Pultrusions could offer a viable alternative to metals in frameworks for roof supports and other applications. Their performance under load can now be predicted with some accuracy. Some possible markets for pultruded composites are: consumer/recreational products; electrical equipment; corrosion-resistance components; transport; and, construction. These are discussed in the article, with emphasis on structural applications.

Holloway, Len (Univ of Surrey, Engl). *Engineering (London)* v 227 n 9 Sep 1987 suppl p 9-10.

## Surfaces

**080355 EFFECT OF RESIN FORMULATION ON THE SURFACE APPEARANCE OF GLASS FIBER REINFORCED POLYMERS.** This paper is concerned with the effect of resin formulation on the magnitude of fiber readout for polymers reinforced with continuous glass fiber mats. The observed fiber readout is the deformation of the surface with a pattern similar to the underlying fibers. In our previous studies, it was established that one of the main factors responsible for fiber readout is the coefficient of linear thermal expansion (CLTE) of the resin in the direction normal to the cosmetic surface. In the current study, the differential thermal contraction between the resin and the glass fibers, a factor directly relatable to the magnitude of fiber readout, has been investigated. This direct relationship was examined by comparing the computed values with the measured magnitude of fiber readout for reinforced polyurethanes (filled with milled glass or hollow glass spheres) and polyesters (filled with calcium carbonate). For all experiments, the predicted values were found to be consistent with the experimental measurements for fiber readout. (Edited author abstract) 11 refs.

**080356 INVESTIGATION OF THE PROCESSES OF ACTIVE AND REPEATED LOADING OF REINFORCED POLYMER MATERIAL AT ELEVATED TEMPERATURE.** The nonlinear theory of the hereditary medium underlies investigation of the processes of active and repeated uniaxial isothermal and nonisothermal loading of the reinforced plastic whose properties depend

essentially on the time of its stay under conditions of elevated temperatures. A nonlinear constitutive equation with the Abel nucleus contains two parameters calculated by instant diagrams of the material strain with several values of holding time at the given temperatures and by creep diagrams at the same temperatures and one stress value. This equation has also been used to calculate certain loading processes whose results are compared with experimental data. ((Author abstract) In Russian. 5 refs.

**Thermal Effects** See Also COMPOSITE MATERIALS—Nonmetallic Matrix Composites.

**080357 THERMAL DAMAGE EFFECTS ON DELAMINATION TOUGHNESS OF A GRAPHITE/EPOXY COMPOSITE.** The effects of overheating AS/3501-6 graphite/epoxy composite material have been examined after exposures in air up to 350°C. Degradation was assessed from measurements of the interlaminar fracture toughness in both Mode I tension and Mode II shear as well as the interlaminar shear strength and hardness. Exposures up to 30 minutes at 225°C and up to 15 minutes at 300°C did not significantly reduce the interlaminar toughness. However, longer exposure at 300°C and short exposures at 350°C produced catastrophic decreases in toughness values, shear strength and hardness. The primary origin of embrittlement was attributed to deterioration of the epoxy as opposed to any fibre or fibre-matrix interfacial weakening. (Author abstract) 13 Refs.

## Thermal Properties

**080358 THERMAL AND RHEOLOGICAL PROPERTIES OF POLY(PHENYLENE SULFIDE) AND POLY(ETHER ETHERKETONE) RESINS AND COMPOSITES.** Poly(phenylene sulfide) (PPS) and poly(ether etherketone) (PEEK) are high performance engineering thermoplastics with a unique combination of excellent environmental, mechanical, and thermal properties. Research on the thermal and rheological properties of PPS and PEEK resins and carbon fiber reinforced prepreps are described. Experimental studies of the dynamic viscoelasticity and thermal properties of these materials are summarized. The effects of processing cycles and environment of the thermal and rheological properties are discussed. The effects of the processing environment and the addition of carbon fiber on the thermal stability are reported. Crosslinking of poly(phenylene sulfide) in air, enhancing thermal stability, is also investigated. (Author abstract) 16 refs.

## Thermoelasticity

**080359 FIBER ORIENTATION AND ITS EFFECT UPON THERMOELASTIC PROPERTIES OF SHORT CARBON FIBER REINFORCED POLY(ETHERETHERKETONE) (PEEK).** Experimental and analytical techniques are employed in the present study to investigate the influence of microstructure on thermoelastic properties of short carbon fiber reinforced poly(etheretherketone). The test specimen geometry is an edge gated, injection molded dogbone tensile bar. Typical of injection

molded structures, three distinct layers of fiber orientation were discernable through the sample thickness. The thermoelastic properties of the surface layer (machined from the specimen) are measured for direct correlation with a micromechanics model. In addition to measuring the volume fractions and constituent properties, microstructural features such as fiber aspect ratio and the process-induced fiber orientation distribution are quantified. Correlation of experimental data with micromechanics model predictions is found to be quite good. (Author abstract) 12 refs.

## Transfer Molding

**080360 MODELING OF PRESSURE DISTRIBUTION IN RESIN TRANSFER MOLDING.** Cavity pressure distribution is the most important parameter to minimize leakage problem at the parting line, to reduce mold deformation and to assure a good quality part. In this paper, a simplified model applicable to unidirectional flow is proposed to predict that pressure. It is based on Darcy's law for flow of liquids through a porous media. The permeability of the reinforcement which is a function of the glass content and characteristic of each type of reinforcement, mat or woven roving, is evaluated. Effects on the model of parameters such as glass density, surface density of the reinforcement and number of reinforcing layers are examined. The mold and instrumentation used to collect data are described and preliminary results are presented for reinforcing mat. (Edited author abstract) 4 refs.

## Waste Disposal

**080361 MANAGING FIBERGLASS-REINFORCED POLYESTER COMPOSITE WASTES.** Fiberglass-reinforced polyester wastes are at present landfilled, which is relatively expensive due to the low bulk density. Based on the experimental results reported here, alternative waste management methods may be proposed. The wastes can be densified before landfilling. This would consist of thermolyzing wastes in the presence of an oxidizing gas at 340-370°C. The weakened composite waste can be ground to powder to increase its bulk density by a factor of 4 or 5. The powder contains fillers and short glass fibers and the mixture could be recycled for low-grade uses. The glass fibers from the waste can be recycled. This is technically feasible, notably after liquid-solid thermolysis. 8 refs.

## Wear See Also COMPOSITE MATERIALS—Wear.

**080362 EFFECT OF STRENGTH DEGRADATION ON WEAR AND FRICTION.** A theoretical expression for wear rate as a function of sliding velocity has been formulated from the concepts of crack propagation, thermal activation, and strength degradation and the analytic results have been tested against the experimental data to provide a comprehensive understanding of this complex behavior. A similar equation describing the relationship between the wear rate and normal load has also been provided. Some thoughts have been given to the atomic chain orientation effect on wear and friction, and also the boundary lubrication phenomena have been described briefly. (Edited author abstract) 29 refs.

Lhymn, C. (Pennsylvania State Univ at Erie, Erie, PA, USA). *Adv Polym Technol* v 7 n 4 Winter 1987 p 365-387.

**080363 LUBRICATED WEAR OF FIBER-REINFORCED POLYMER COMPOSITES.** The specific

wear rates of fibrous polymer composites in water and oil lubricants were investigated by means of tribological data, microscopy, and phenomenological modeling. The wear rate is a function of mechanical, tribological, and material parameters, and a theoretical expression of wear rate has been derived from the concepts of crack propagation, damage accumulation, and classical mechanics. The observed wear rate data as a function of sliding velocity or normal load appear to be explainable using the proposed wear equation. (Author abstract) 55 refs.

Lhymn, C. (Pennsylvania State Univ, Erie, PA, USA). *Wear* v 122 n 1 Feb 15 1988 p 13-31.

**080364 TRIBOLOGICAL PROPERTIES OF SILICONE-IMPREGNATED POLYMER COMPOSITES-TWO-BODY ABRASION ?.** The friction and wear behavior of silicone-impregnated fiber-reinforced thermoplastics has been investigated as a function of normal load in air, water, and oil lubricants using a two-body abrasion tester. The measured tribological data have been phenomenologically explained by a wear/friction equation derived from the concepts of crack propagation and wear failure mode. The wear characteristics of polyethylene terephthalate, polybutylene terephthalate and nylon thermoplastics reinforced with various fibers and fillers are covered. (Edited author abstract). 13 Refs.

### Applications See SOILS—Stabilization.

### Coextrusion

**080366 MULTILAYER SHEET COEXTRUSION: ANALYSIS AND DESIGN.** A numerical simulation of multilayer coextrusion flows has been undertaken for polymer melts used in producing multilayered plastic sheets. Viscosity data and other material properties are used for typical melts and adhesives applied in coextrusion. Industrial designs have been employed for feedblock geometry and multimanifold vane flat dies. The analysis is based on the lubrication approximation theory (LAT), which treats the flow locally as fully developed. A Newton-Raphson iterative scheme is employed to solve the equations for a pressure-driven flow of N number of layers ( $N \leq 11$ ). Such an analysis provides a quick qualitative as well as quantitative insight into the proper design and melt combinations for multilayer sheet coextrusion. (Edited author abstract). 22 Refs.

Mitsoulis, Evan (Univ of Ottawa, Ottawa, Ont, Can). *Adv Polym Technol* v 8 n 3 Fall 1988 p 225-242.

## Crack Propagation

**080367 ANALYSIS OF CRACK-INDUCED-CRAZE IN POLYMERS.** In this paper, the viscoelastic boundary element method is used to estimate the opening displacement and the envelope stress on the surface of an isolated crack-induced-craze system. To predict the propagation history of both the crack and the craze in a polymer sheet, the material properties of the glassy polymers are represented by a generalized linear viscoelastic model. A sequence of numerical calculations of crack-induced-craze propagation by means of the boundary element method are carried out. Results are compared with the theoretical micromechanics predictions. Good agreements are obtained. This investigation illustrates that the three-step envelope stress profile is reasonably adequate for use in analysing polymer quasifracture problems. The stress concentration phenomenon is taken into consideration in the present work. (Edited author abstract). 44 Refs.

**080368 MICROSTRUCTURE AND MECHANICAL BEHAVIOR OF REINFORCED REACTION INJECTION MOLDED (RRIM) POLYURETHANE.** A study was carried out to characterize the microstructure and distribution of some mechanical properties in reinforced reaction injection molding panels (RRIM). The panels were prepared under a variety of processing conditions. Scanning electron microscopy, differential scanning calorimetry, and Fourier transform infrared analysis were employed for microstructure characterization. The results indicate significant relationships between processing conditions, microstructure, and mechanical properties. The balance between the distributions of cure and crystallinity, which is difficult to define clearly, plays an important role in determining panel behavior. (Edited author abstract) 14 refs.

**080370 EXPERIMENTAL AND ANALYTICAL PROCEDURES FOR FLOW DYNAMICS OF SHEET MOLDING COMPOUND (SMC) IN COMPRESSION MOLDING.** A package of procedures have been developed to collect and analyze the response of dynamic variables such as pressure, temperature, and mold separa-

tion during the compression molding of Sheet Molding Compound (SMC). The molded SMC consists of a thermoset polymeric matrix and chopped glass fibers. From the dynamic responses, the molding process was found to consist of two regions: the flow and the subsequent curing reaction region. With an R-25 formulation and a mold closing rate of 30 mm/s, these two regions are well separated and the average flow time is not significantly affected by the maturation time for the material up to 30 days. Several mechanical parameters were estimated based on relatively simple flow models. (Edited author abstract) 23 refs.

**080371 SHEAR FATIGUE EVALUATION OF SMC.** The failure mode of automotive parts made of sheet molding compound often involves in-plane shear. Fatigue data are presented for three ratios of minimum/maximum shear stresses. Interpolation yields shear fatigue strength data for other stress ratios. (Author abstract)

Freeman, Richard B. (Budd Co, Fort Washington, PA, USA). *Mod Plast* v 64 n 10 Oct 1987 p 96, 98, 100.

**080372 INSERTS FOR FASTENING SHEET MOLDING COMPOUNDS.** New stainless steel inserts are developed for fastening sheet molding compound (SMC). Using these molded-in inserts, SMC components can be assembled without protrusions. The inserts consist of two mating surfaces which interlock through the existence of a shoulder male boss and a shoulder female counterbore. Repeated assembly and disassembly can take place without damaging the material being fastened. The strength of the joint, when using these interlocking inserts, is comparable to that when using bolts. Also being investigated is the strength of the joint after being immersed in water for half a month. The difference between the dry and wet strengths for the inserted samples is less than that for the bolted samples. Load versus extension plots show that these particular inserts provide a more rigid joint than a bolted connection. (Author abstract) 4 refs.

**080373 BOUNDARY ELEMENT ANALYSIS OF FLOW IN SHEET MOLDING COMPOUND.** A new boundary element method has been developed for analyzing the flow of sheet molding compound (SMC) during compression molding. The boundary element equations can be used to determine the velocities on the perimeter of the charge. Successive flow front configurations are then generated by a simple explicit updating procedure. This approach was used to predict the flow front progression for elliptical, rectangular, and L-shaped charges. Comparisons with experimental data for elliptical and rectangular charges were encouraging. The fact that it was possible to obtain reasonable agreement for charges with different shapes and thicknesses lends support to the underlying flow model. Furthermore, valuable insight regarding knit line formation was acquired by analyzing the L-shaped charge. Results from the boundary element analysis showed that the initial thickness of the charge has a pronounced effect on knit line development. Even though there is considerable industrial experience in making SMC parts, the important role of charge thickness on knit line formation appears to have been largely overlooked. Prior analyses gave no indication of this effect because they were based on lubrication models that were independent of charge thickness. (Author abstract) 12 refs.

**080374 MECHANICALLY FASTENED JOINT BEHAVIOR IN SHEET MOLDING COMPOUND (SMC).** This paper presents experimental data of mechanical joints in sheet molding compounds (SMC). Double lap specimens were employed to evaluate strength and failure

mode as a function of joint geometry, environmental temperature, and fiber contents. The failure modes are classified into three types: multiple, net tension, and bearing mode. In order to predict the load-bearing capabilities in each failure mode, a procedure with specimen strength and configuration is proposed. This method is applied to various environmental temperatures and fiber contents. (Author abstract) 12 refs. In Japanese.

**080377 EFFECT OF ASYMMETRICAL CONFIGURATION OF RIB PARTS ON DEFECTS OF SMC PRODUCTS.** The SMC has been developed as a material for the mass production system using press moulding, but some problems arise due to its heterogeneity caused by fibre orientation. The faults observed in the products, such as the appearance of brittle regions in the resin-rich parts or at the weld lines and the surface sink produced at the convex parts, may be regarded as the moulding problems. The purpose of this study was to prevent the above troubles and to construct the CAD system for SMC press moulding process. The case of the symmetrical configuration with one rib part in full charge was treated in the previous paper. In this paper, the effect of asymmetrical configuration with one or two rib parts was investigated to solve the above problems associated with the flow state through the evaluation of flexural strength determined after observation of the material flow state. The analytical method was established by using a linear incremental finite element method. (Edited author abstract). 4 Refs. In Japanese.

**080380 GENERAL RESULTS ON THE FLOW OF CHOPPED FIBER COMPOUNDS IN COMPRESSION MOLDING.** Two main theorems are proved from the governing differential equations for the flow of sheet molding compounds in compression molding. The first states that among all possible velocity distributions which satisfy the incompressibility condition and the kinematic boundary condition at a fixed edge, the actual solution minimizes the instantaneous rate of work by the molding press. The second is a general representation theorem for the velocity solution in terms of two scalar potentials. One of these potentials satisfies Laplace's equation and the second satisfies Helmholtz's equation. Each of these theorems is applied to problems of practical interest. The variational theorem is used to obtain a simple approximate solution for the flow front progression in a rectangular charge which, for a limited range of parameters, agrees remarkably well with previous numerical solutions of the exact equations. The representation theorem is used to examine the form of the solution in the important practical limit of a thin cavity. (Edited author abstract). 7 Refs.

**080381 COST-EFFICIENT SMC BONDING THROUGH SUPPLIER TEAMWORK.** A discussion is presented of methods used to upgrade one firm's structural bonding systems. The first step involved a thorough investigation of the new adhesive systems that have revolutionized structural bonding. Given the application and the variety of problems that needed to be addressed, a two-part epoxy adhesive that can be heat cured for fast bonding or cured at room temperature was installed. The equipment that was finally settled on is air-draulically driven, providing a high degree of mixed material flow control at the dispense point. A number of other power options are available, including servo motor-driven systems for robotics applications. The systems may be stationary or portable. One of the system's most notable features is its mix-at-the-nozzle automatic dispense valve design. The two components are line-fed to the valve from the positive displacement metering cylinders. The materials come together for the first time in the nozzle, preventing the material from curing inside the valve. A special static, motionless mixer combines the two-part epoxy in the disposable nozzle as the adhesive is dispensed.

**080382 POLYESTER MOULDING COMPOUNDS.** Polyester moulding compounds are moulding materials that can reproduce the excellent properties of glass reinforced plastics (GRP), colloquially known as fiberglass, on a volume production basis. Whereas GRP parts are produced by a labor intensive manual process, polyester moulding compounds enable the types of moulding processes used for other plastics to be employed. The two main types of polyester compounds used are sheet moulding compound (SMC) and dough moulding compound (DMC). Both materials are based on the same basic raw materials, polyester resins, glass fibers, fillers, and other minor additives, the main difference between the two

types being the length of the glass fiber employed, the fiber length dictating both the properties of the material and the form in which it is supplied.

## Stability

**080383 LONG-TERM STABILITY OF WASTE LANDFILL SEALING SHEET MADE OF POLYETHYLENE.** Bottom liners of waste landfills protect the ground-water from leachate which may contain hazardous substances. Intermediate coverings installed during the operation of the landfill unit help to minimize leachate from waste and to prevent landfill gases from escaping. After the closure of the unit, the sealing system must keep functioning for as long as hazardous leachate still results. As the inaccessibility of the bottom liner rules out repair at a later date, high demands must be made on the durability of the material and the quality of the construction work. Landfill bottom liners are made of both mineral materials (clay and/or loam) and plastic sheets. Some of the topics discussed are creep-rupture strength of plastic sheet, strength of welds and chemical resistance.

## Testing

**080384 INSTRUMENTED FALLING WEIGHT IMPACT TEST OF POLYMER SHEETS.** The response of polypropylene (PP), polycarbonate (PC), polystyrene (PS), polyethylene (PE), propylene-ethylene block copolymer (PPB), and acrylonitrile-butadiene-styrene (ABS) sheets has been studied using an instrumented falling weight impact tester. Three modes of fracture occur: puncture failure, crack failure, and brittle fracture, depending on their ductility and mechanical properties. (Edited author abstract) In Japanese. 4 refs.

**080385 FINITE ELEMENT MODEL OF VISCOELASTIC MEMBRANE DEFORMATION.** A numerical scheme is presented for modelling the axisymmetric inflation of a thin incompressible isotropic sheet up to a rigid obstacle under the action of a uniform pressure. A membrane model is assumed for the behaviour of the sheet. When the sheet makes contact with the obstacle it is further assumed that a condition of total sticking occurs. In the scheme the equilibrium and constitutive equations are kept separate and a modified  $H^1$ -Galerkin technique using cubic Hermite approximations is employed. Numerical results are presented for the cases of both flat and elliptical obstacles and for both materials of the Mooney-Rivlin elastic type and of a viscoelastic generalization of the Mooney-Rivlin model. (Author abstract) 6 refs.

**080386 DEEP DRAWING OF POLYPROPYLENE SHEETS UNDER DIFFERENTIAL HEATING CONDITIONS.** Means of improving the deep drawability of thermoplastic sheets were explored by introducing temperature gradients in the deforming material during deep drawing of initially flat sheets. The specific experimental procedure consisted of either limiting the heating to the flange section of the deforming sheet of exposing the entire material to higher temperatures. At the same time, the initial blank size and the clamping force at the flange section were varied systematically. Both polypropylene and polypropylene with 40 percent calcium carbonate in

the form of sheet were tested up to 130°C. It is demonstrated that the drawability increases markedly with increasing temperature gradient between the flange and punch sections. (Edited author abstract) 24 refs.

## PLASTISOLS

**080387 THERMODYNAMIC APPROACH TO THE FORMULATION OF PRINCIPLES FOR THE PREPARATION OF PLASTISOLS.** A thermodynamic standpoint is discussed in regard to the choice of the means whereby the introduction of solid and liquid into multicomponent plastisols may be effected. It was found that if the distribution of liquid components among solid ones during the preparation of a plastisol is carried out in such a way as to bring the system as close as possible to the thermodynamic equilibrium state, the result will be that a very significant increase in the stability of the viscosity of the plastisol will thus be obtained. (Author abstract) 4 refs.

Guzeyev, V.V. (A.M. Gorkii State Univ of the Urals, USSR); Yushkova, S.M.; Berezov, L.V.; Mozhukhin, V.B.; Vanina, G.V.; Tager, A.A. *Polym Sci USSR* v 23 n 12 Dec 1987 p 2900-2905.

## Physical Properties

**080388 MORE MEANINGFUL MEASUREMENT OF PLASTISOL PROPERTIES.** The fundamentals of plastisol rheology must be understood in order to properly select and utilize plastisol property measurements. Useful evaluation should also be made of the rheological effects of formulation ingredients and their interrelationships. Other factors such as plastisol preparation, storage conditions, process shear rates, temperatures, dwell times, and finished product specifications will influence the design of effective test procedures. Once meaningful plastisol property measurements have been developed, better quality control assurance results, and in addition quality, productivity, and profitability improvements are effected. (Author abstract) 4 refs.

**080391 COMPRESSIVE BEHAVIOR OF GUSSET PLATE CONNECTIONS.** The compressive behavior and buckling strength of thin-walled gusset plate connections were examined on the basis of an experimental investigation of full-scale diagonal bracing connections. Such connections are commonly used to transfer forces from a bracing member to the beam and column through the gusset plate. A total of 14 tests were run on six connections specimens. Plate thickness, geometric configuration, boundary conditions, eccentricity and reinforcement were considered in planning the tests. Attempts were made to correlate the eccentric loading test results with the beam column formulas and the concentric loading test results with the finite element program BASP. Comparisons are shown to be in reasonable agreement. Current design practices are discussed briefly and found to be very unconservative compared with test results. A parametric study was undertaken by using different thickness and size of gusset plates, different thickness of splice plate and different boundary conditions. A tentative design guideline for gusset plate loaded in compression is proposed based on test results and parametric studies. (Edited author abstract) 18 refs.

**080392 DREISEITIG GELAGERTE RECHTECK-PLATTEN AUF ELASTISCHER BETTUNG.** [Rectangular Plates Supported on Three Sides by Elastic Bedding]. The submitted contribution offers a collection of moment tables enabling the rapid calculation of the essential plate moments of rectangular plates supported on three sides by elastic bedding. The basic analytic method of the Fourier series of sines for compiling these tables has been developed in the author's previous publications and specified in detail. This method made it possible to treat plates with two opposite hinged edges. Generally, for practical application, the determination of two settling states is required (uniform settling, linear progressive settling), to make allowance for the position of the resultant of the vertical load F. Finally, the method of calculation is illustrated by means of a detailed numerical example, and compared with the results obtained, if one presupposes that soil pressure is linearly distributed. (Author abstract) In German. 3 refs.

Hraby, Konrad. *Bautechnik* v 65 n 1 Jan 1988 p 27-31.

**080393 DYNAMIC PLASTIC RESPONSE OF CIRCULAR PLATES IN A DAMPING MEDIUM.** The motion of a simply supported circular plate of rigid-plastic material is studied. The motion is produced by a uniformly distributed impulsive velocity. The material of the plate is assumed to obey the Tresca yield criterion with the inclusion of shear yield. The effect of damping by the surrounding medium on the plate motion is examined. (Author abstract) 6 refs.

Kumar, Ashwini (IIT Kanpur, Kanpur, India). *Int J Impact Eng* v 6 n 4 1987 p 285-290.

**080394 IMPACT OF A CYLINDRICAL OR RECTANGULAR INDENTER AGAINST A THERMOELASTIC-PLASTIC PLATE WITH CAVITIES.** The present paper deals with numerical modeling of nonstationary thermoelastic-plastic processes initiated by contact interaction between axisymmetric or rectangular solids. We present the constitutive relations of the coupled theory of thermoelastoplasticity, based on the unified curve concept; to integrate them numerically, we set up an iterative difference ripple-through calculation scheme. Analysis of the numerical data makes it possible to determine the principal behavior of the stressed and kinematic state of a multilayer plate with cavities under the impact of a deformable indenter that is shaped like a cylinder of variable radius or a rectangular beam. (Edited author abstract) 7 refs.

Rimskii, V.K. *Mech Solids* v 22 n 3 1987 p 106-112.

**080395 STRESSES ROUND CIRCULAR HOLES AND INCLUSIONS.** The stress distribution around a circular hole in a plate in uniaxial tension is well known: at the ends of the diameter aligned with the tension (the 'poles') there is a hoop stress of  $-T$ ; at the ends of the transverse diameter (the 'equator') the hoop stress is  $+3T$ . By superposition of two such tensions (usually unequal) we arrive at the stresses around a hole in any uniform stress field, or, equivalently, around a small hole in an arbitrary non-uniform stress field. If the hole is not small an obvious first approximation is to apply the same stress concentration factors to the stresses at the center of the 'hole', i.e. to the stresses which exist at the center of the circle where the hole is to be. This paper addresses the question of how good this approximation is, and whether it can be improved upon. 6 Refs.

**080396 TRANSFER ADMITTANCE OF A POINT-EXCITED, FLUID-LOADED PLATE.** This paper concerns the evaluation of the transfer admittance of an infinite, thin, fluid-loaded, elastic plate excited by a point force as a function of radial distance between forcing and response, and frequency. The plate vibration is expressed in terms of a sum of residues and a branch-line integral. These results lend themselves to rapid numerical evaluation for specific cases. Special consideration is given to the plate response in two limits. In the first, it is shown that the major component of the surface response is a subsonic free wave, while in the second, it is shown that the response is dominated by a 'leaky' wave whose characteristics tend in the limit to those of a flexural wave of the plate vibrating in vacuo. (Edited author abstract) 17 refs.

**080397 ACOUSTO-ULTRASONIC INPUT-OUTPUT CHARACTERIZATION OF UNIDIRECTIONAL FIBER COMPOSITE PLATE BY SV WAVES.** A unidirectional fiberglass epoxy composite specimen is modeled as a homogeneous transversely isotropic continuum plate medium. Acousto-ultrasonic non-contact input-output characterization by tracing SV waves in the continuum is studied theoretically with a transmitting and a receiving transducer located on the same face of the plate. The isotropic plane of the equivalent continuum plate model lies in the midplane of the plate and is parallel to the top and bottom faces of the plate. This study increases the quantitative understanding of acousto-ultrasonic nondestructive evaluation (NDE) parameters such as the stress wave factor (WSF) and wave propagation in fiber reinforced polymeric, ceramic or metallic composites. #### Acoustic Wave Effects

**080398 ETUDE EXPERIMENTALE DES EFFETS NON GEOMETRIQUES LIES A L'INTERACTION D'UN FAISCEAU ACOUSTIQUE BORNE AVEC UNE PLAQUE PLANE IMMERGEE.** [Experimental Study of Non-Geometrical Effects Resulting from the Interaction of a Bounded Acoustic Beam with a Plane Plate Immersed in Water]. When a bounded acoustic beam is incident on a plate immersed in a fluid, Lamb modes are generated at particular angles of incidence. For these critical angles non-specular effects are found; they concern the reflection and transmission coefficients and also the intensity distribution. In this paper we study these effects experimentally. Particular attention is devoted to the influence of the angle of incidence, the thickness of the plates and the beamwidth. The experimental curves are compared with the theoretical calculations developed by Ngoc and Mayer, and good agreement is observed. (Author abstract) In French. 10 refs.

#### Aerodynamics

**080399 ANALYSIS OF APPROXIMATIONS OF AERODYNAMIC COEFFICIENTS OF THIN BODIES IN A RAREFIED GAS.** A regression analysis is made of the approximation of the relationships between exchange coefficients and local incidence angle. The results of a numeric investigation of the aerodynamic characteristics of a plate are used for the analysis. The approximation contains three parameters (two for the aerodynamic longitudinal force coefficient and one for the aerodynamic lift coefficient), which must be determined from an experiment. For these parameters an analytic approximation of their dependency on the Knudsen (Reynolds) number is suggested. (Author abstract) 7 refs.

Naritsa, V.S. *Leningrad Univ Mech Bull* n 2 1987 p 67-70.

**Aluminum** See Also ALUMINUM AND ALLOYS—Welding.

**080400 NONLOCAL DAMAGE THEORY.** A nonlocal damage field theory is proposed and a response model of nonlocal elastic damage is given. A simulating experiment using aluminum alloy plates with arrays of holes shows that the load bearing capacity of a plate varies with angle  $\gamma$  between array and loading direction. The characteristics and attenuation lengths appreciably affect the constitutive equations. (Author abstract) 13 refs.

Xia, Shaobo (Huazhong Univ of Science & Technology, Wuhan, China); Li, Guangxia; Lee, Hao. *Int J Fract* v 34 n 4 Aug 1987 p 239-250.

**080401 SHEAR EFFECTIVE WIDTH OF ALUMINIUM PLATES.** The capacity of a plate to sustain shear load greater than the critical load is studied. The concept of effective width for square plates loaded in shear is developed to consider rectangular plates loaded in shear. The deformation of the plate at failure is formulated. Very good agreement is observed between the theoretical results and experimental measurements carried out on aluminum web plates. (Author abstract) 4 refs.

**080405 APPROXIMATE SOLUTION OF THE AXISYMMETRIC VON KARMAN EQUATIONS FOR A POINT-LOADED CIRCULAR PLATE.** A closed-form solution of the axisymmetric von Karman equations or their equivalent for a point-loaded circular plate continues to evade researchers. An approximate solution is presented which consists of general equations which are easy to use and which compare well with other solutions including the previously unpublished numerical results of Brodland. The transverse deflection is given by an assumed expression which contains a single parameter associated with plate shape. This parameter,  $\beta$ , is determined by minimizing a shear-related residual. Thus, the present analysis takes advantage of the ease with which assumed-form solutions can be used, while ensuring that the shape change which occurs with increasing load can be accommodated. 15 refs.

Dolovich, A.T. (Univ of Waterloo, Waterloo, Ont, Can); Brodland, G.W.; Thornton-Trump, A.B. *J Appl Mech Trans ASME* v 55 n 1 Mar 1988 p 241-243.

**080406 THIN PLATE ELEMENT WITH RELAXED KIRCHHOFF CONSTRAINTS.** An analysis of thin plates by  $C^0$  elements is presented. The fundamental part of it is the formulation of a set of constraints that relate the rotational degrees of freedom to the translational degrees of freedom and which are weaker than the usual Kirchhoff constraints. A penalty term associated with these constraints is then introduced instead of the usual expression for the shear strain energy. It is shown that the approach is effective for both quadrilateral and triangular elements. (Author abstract) 37 refs.

**080408 SOLUTION OF CONTACT PROBLEMS FOR PLATES ON AN ELASTIC HALFSPACE.** The method of nonlinear boundary equations is used to formulate and solve problems of plate contact with an elastic halfspace. This approach, together with modern methods of operator-equation theory, allows the existence and uniqueness of solutions and also some of their properties to be investigated relatively simply in very general cases. In addition, there is the possibility of using well-known methods of solving nonlinear operator equations for the solution of these problems. 6 refs.

Galanov, B.A. (Acad of Sciences of the USSR, Kiev, USSR); Nikol'skii, Yu.V. *Sov Appl Mech* v 23 n 8 Aug 1987 p 722-728.

**080409 ON THE INTERACTION BETWEEN AN EDGE DISLOCATION AND TWO CIRCULAR INCLUSIONS IN AN INFINITE PLATE (2ND REPORT, WITH THE GLIDE PLANE INCLINED TO THE X-AXIS).** To continue the work presented in the previous paper, the solution to the problem of the interaction between two circular inclusions and an edge dislocation in an infinite plate, which are arranged in the order of inclusion-edge dislocation-inclusion, and are placed on the x-axis, having the glide plane inclined to the x-axis. Results obtained by numerical calculation indicate that, for the region near the interface, the interactions are affected by the combinations of elastic constants and the inclination of the glide plane. The dislocation has a stable equilibrium position or an unstable equilibrium position at some intermediate distance from the inclusions under some combinations of elastic constants. The equilibrium positions are also affected by the inclination of the glide plane. (Author abstract) In Japanese. 11 refs.

**080410 INITIAL-VALUE ANALYSIS OF CONTINUOUS ORTHOTROPIC PLATES.** A numerical procedure is presented which is called the initial-value method to analyze continuous orthotropic plates. The method consists of integrating in one direction and using finite difference expressions for the other direction. The procedure of the initial-value method is discussed in detail. The method has proven its efficiency in the analysis of single-span beams and plates. The convergence of the method is discussed in a few examples. The effects of changing the number of elements in each direction on the percentage error and computation time are shown. Several examples are presented to compare this method with other approximate methods. Deflections and moments are presented in tabular form for various aspect ratios and degrees of orthotropy for two cases of continuous plates. (Edited author abstract). 6 refs.

Al-Khaiat, Husain (Kuwait Univ, Kuwait). *Comput Methods Appl Mech Eng* v 69 n 2 Jul 1988 p 153-165.

**080411 ANALIZA EXCENTRYCKY VYZTUZENYCH TENKYCH DESEK.** [Analysis of Thin Plates With Eccentric Stiffeners]. Thin steel isotropic and stiffened plates loaded in compression and bending are analyzed. The theory is based on the large deflection von Karman-Marguerre plate equations. Plasticity is handled by Crisfield's 'area' incremental approach using Ilyushin-Ivanov's yield surface. Bending and axial rigidities of

stiffeners were introduced into solution by interaction forces along the stiffener-plate connection. It is shown that careful formulation of stiffener boundary conditions is needed because of possible changing of mode of collapse. The numerical procedure uses finite differences and interlacing meshes solved by dynamic relaxation. (Edited author abstract). 37 Refs. In Czech.

**Applications** See HEAT EXCHANGERS—Design; SOILS—Testing.

#### Assembly

**080413 FINITE STRIP METHODS FOR INSTABILITY OF PRISMATIC PLATE ASSEMBLIES.** The fundamentals and applications of the Finite Strip Method to instability of prismatic plate assemblies are reviewed. In the first part of the paper the motivation to study such stability problems in the context of civil engineering structures is stated. In the second part both the energy concepts of stability from which the equilibrium equations are obtained, and the displacement fields used for the finite strip approximations are discussed. The last part is oriented to applications of the stability and finite strip fundamentals to the solution of bifurcation buckling, post buckling equilibrium and mode interaction. The applications show that the technique is capable of handling almost every problem of stability of prismatic plate assemblies, with the restrictions of the boundary conditions that can be satisfied in global buckling problems. (Author abstract). 18 Refs.

**080414 CALCULATION OF ELASTIC PLATES UNDER A COMBINED LOAD.** The solution of the problem of bending under the combined effect of transverse loading and of the forces acting in the median plane is considered. The method of R-functions used successively to solve the plane problem of the theory of elasticity and then the problem of plate bending makes it possible to automate the process of solving the initial problem for plates of virtually arbitrary shape and various loading methods. Numerical results are presented for a square, freely supported plate weakened by a central circular hole, subjected to the effect of a transverse load and compressive forces. 5 refs.

Rvachev, V.L. (Acad of Sciences of the Ukrainian SSR, Kharkov, USSR); Kurpa, L.V.; Shevchenko, A.N. *Sov Appl Mech* v 23 n 3 Mar 1987 p 256-260.

**080415 NEW TYPE OF PLATE BENDING ELEMENT.** Based on a two-field generalized variational principle, a new type of arbitrary quadrilateral plate bending element, with four nodes and with the effect of transverse shear deformation taken into account, is

proposed. The element is applicable to a wide range of plate thickness and an explicit expression of stiffness matrix can be obtained. Therefore, it possesses the distinguished features of general applicability, high precision and less computer time. (Author abstract) 12 refs.

**080416 ELASTIC PLATES UNDER BENDING SOLVED BY PSEUDOCAUSTICS.** The method of pseudocaustics was applied to the study of out-of-plane bending in elastic plates. It is shown that for bending problems where the loading mode is given, the method determines experimentally the complex potential function at selected points along the boundaries. A conformal mapping of the closed smooth curves of each boundary of the plate on to a unit circle allows the determination of the complex potential  $\phi(z)$ , expressed in the form of a Laurent series. This in turn yields the complete solution of the bent plate. In order to show the efficiency of the method it was applied to two typical examples of thin infinite plates in cylindrical bending, having either a circular central hole, or a square hole. (Edited author abstract) 10 refs.

**080417 IMPROVED DYNAMIC RELAXATION METHOD FOR THE ANALYSIS OF PLATE BENDING PROBLEMS.** An improved dynamic relaxation method is used to solve the set of simultaneous equations resulting from application of the finite element method for plate bending problems. Different weights are used as multiplying factors for each mass and damping factor in each equation representing one of the three degrees of freedom at each node. The optimum values of these weights are obtained for different cases of the bending of cantilever plates stiffened with edge beams with different sizes of stiffening edge beams. (Author abstract) 8 refs.

**080419 TRANSVERSE SHEAR OSCILLATIONS IN FOUR-NODE QUADRILATERAL PLATE ELEMENTS.** Numerical results show that the transverse shears are free of oscillation for regular or quasi-regular meshes of four-node plate elements based on Mindlin-Reissner theory. However, even small perturbations of these meshes can introduce severe oscillations throughout the mesh. These findings apply to the underintegrated elements with and without stabilization and to the fully integrated elements which use assumed shear strains. A filtering procedure capable of recovering improved shears is presented. (Author abstract) 16 refs.

**080420 BASIC STUDY OF THE ACCURACY ESTIMATION OF STRUCTURAL ANALYSIS BY THE ZOOMING METHOD [2ND REPORT, FINITE ELEMENT ANALYSIS OF THE TRANSVERSE BENDING OF THIN FLAT PLATES (PART 2)].** As a basic study for the establishment of an accuracy estimation method in structural analysis using the zooming method, this second report deals also, as previous report, with the

finite element analysis of the problems of transverse bending of thin, flat plates. In the previous report, we treated a small hole, if it was in a plate, as a hole. This treatment inconveniently led to an increase of nodal points and hence to an increase of the size of the system of simultaneous linear equations and computation time. To overcome this inconvenience, we propose in this second report a method where small holes are neglected and the whole region is divided into elements of nearly equal size at the initial two or more analyses prior to the start of the zooming method with consideration of holes. (Edited author abstract) In Japanese. 4 refs.

**080421 SPREADSHEET SOLUTION OF ELASTIC PLATE BENDING PROBLEMS.** This paper discusses the use of spreadsheet programs for the analysis of slab systems. The objective is to demonstrate a practical approach which can be employed for preliminary analysis, checking of mainframe solutions, or complete analysis of less complicated slab systems. Other than word processing, the most popular use of microcomputers is for 'spreadsheet' analysis of problems. The software is inexpensive, relatively easy to learn, and a highly versatile and productive tool. This paper will develop a technique which allows engineers to easily model elastic slab bending problems using readily available microcomputer spreadsheet programs. A 'central difference' formulation of the problems is used because the operators are well suited to spreadsheet modeling. Generation of the operators is illustrated using the finite difference method. A compatibility approach is developed for the inclusion of beams in the model. Accuracy, convergence, and mesh size are all discussed. Several examples showing iterative solution of both classical and practical plate problems are shown. 10 refs.

**080422 STRESS CONCENTRATION OF A STRIP WITH A SINGLE EDGE NOTCH.** This paper deals with the stress concentration analysis of a semicircular and a 60° V-shaped single edge notch in an infinite strip under three different types of loading conditions: (a) uniform tension, (b) in-plane bending and (c) pure tension. The stress field induced by a point force in the semi-infinite plate, Green's function in a closed form, is used to solve those problems. The results show that Neuber's formula gives an underestimated stress concentration factor when the notch is sharp and shallow. The stress concentration factors of 60° V-shaped notches are represented by diagrams for wide use. (Author abstract) 5 refs.

**080426 REFINED HERMITIAN ISOPARAMETRIC PLATE BENDING ELEMENT.** A refined version of the Hermitian isoparametric element which avoids the difficulties with derivative parameters in the geometric mapping is presented. The accuracy of the element is compared with the DKT-triangle, which is considered to be the most accurate 9 degrees-of-freedom plate bending element. The present element compares rather well with the DKT element. Moreover, comparisons are also made in some 'non-standard' cases (circular plate with concentrated load off the centre and elliptical plate) which suggest that the accuracy of all the elements considered is slightly poorer in these than in the standard cases. (Author abstract) 13 refs.

**080427 STUDY OF THE INFLUENCE OF THE ANGLE CONDITION ON PLATE BENDING OF TRIANGULAR FINITE ELEMENTS.** In triangulating a domain to find a finite element approximation for the solution of a specific problem, the so-called angle condition is essential. In this paper, a study of the effects of this condition on the spectral properties of the stiffness matrix has been performed for two plate bending elements: the constant moment triangle (CMT) and the discrete Kirchhoff triangle (DKT). This has been done on the element level and also for the global system. It is shown that as the smallest, rather than the largest, angle of the elements considered herein decreases, the condition number of the global stiffness matrix increases. (Author abstract) 8 refs.

**080428 MECHANICS OF THE FLAME BENDING PROCESS: THEORY AND APPLICATIONS.** The flame bending process can be most useful in the present effort to automate the plate bending process in shipyards. To achieve this goal, the complicated thermo-elastic-plastic behavior of the plate during the process must be understood. A review of the past analytical research efforts reveals that these attempts have been restricted to beam bending. Here a theory for the thermo-elastic-plastic plate bending is developed. Furthermore, using a boundary element method as a solution technique, the difference between the mechanics of beam bending versus plate bending is shown. Recommendations for future work are given. (Author abstract) 31 refs.

**080430 FLEXURAL ANALYSIS OF LAMINATED COMPOSITES USING REFINED HIGHER-ORDER C PLATE BENDING ELEMENTS.** A finite element formulation for flexure of a symmetrically laminated plate based on a higher-order displacement model and a three-dimensional state of stress and strain is presented here. The present higher-order theory incorporates linear variation of transverse normal strains and parabolic variation of transverse shear strains through the plate thickness, and as a result it does not require shear correction coefficients. A nine-noded Lagrangian parabolic isoparametric plate bending element is described. The applications of the element to bending of laminated plates with various loading, boundary conditions, and lamination types are discussed. (Edited author abstract) 26 refs.

**080431 SIMPLE MODEL FOR THE CONTACT PROBLEM OF A FINITE CRACKED PLATE IN BENDING.** In bending of a finite cracked plate, the stress intensity factor (SIF) at a cracked tip is usually negative. This means that the displacement at the vicinity of the crack tip is overlapped. However, this is not reasonable. In this paper a simple model is suggested. When the SIF is negative, some part of the crack will close. By using a collocation method the length of the closed part of the crack, and the SIF value of the other crack tip have been calculated. (Edited author abstract) 5 refs.

**080432 REFINED HIGHER-ORDER GENERALLY ORTHOTROPIC C<sup>0</sup> PLATE BENDING ELEMENT.** A finite element formulation for flexure of a generally orthotropic plate based on a higher-order displacement model and a three-dimensional state of stress and strain is presented here. This higher-order theory incorporates linear variation of transverse normal strain/stress and parabolic variation of transverse shear strains through the thickness of the plate. The nine-noded quadrilateral from the family of two-dimensional C<sup>0</sup> continuous isoparametric Lagrangian elements is then developed as a generally orthotropic higher-order element. The performance of this element is evaluated on square plates with different support conditions and under uniformly distributed and central point loads. The numerical results of the present formulation are compared with thin plate, elasticity and Mindlin/Reissner solutions. The effect of degree of orthotropy of the maximum bending moment location is examined for different loading and boundary conditions. (Edited author abstract) 23 refs.

**080433 ANALYSIS OF SKEW AND TRIANGULAR PLATES IN BENDING.** The objective of this paper is to develop fast converging series solutions for rectangular, parallelogram and triangular plate bending elements with arbitrary boundary conditions and arbitrary shapes, and subjected to generalized normal loading. Solutions to parallelogram and rectangular plates are obtained by representing the deformed shape of a structure by a sequence of functions that are complete and satisfy the natural and forced boundary conditions. These consist of

a combination of trigonometric and polynomial functions with undetermined coefficients. The undetermined coefficients are determined by using modified Galerkin technique, and satisfying the boundary conditions. Solutions of triangular plates for simply supported and clamped boundary conditions are obtained in a similar manner by selecting appropriate shape functions that satisfy the natural and forced boundary conditions. (Edited author abstract) 32 refs.

**080434 FINITE ELEMENT MODELS FOR STIFFENED PLATES UNDER TRANSVERSE LOADING.** Linear finite element models based on Mindlin's shear distortion theory for bending of eccentrically stiffened plates subjected to transverse loading are presented. Two models using discrete plate-beam formulations are given and the superiority of one over the other is discussed. An additional formulation applicable to technically orthotropic plates under distributed loading is included. This latter formulation may sometimes be advantageous under less demanding conditions because of reasons of economy. (Author abstract) 10 refs.

**080435 PLATE BENDING ANALYSIS USING MACRO ELEMENTS.** A variable degree of freedom plate bending element is presented. The displacement function within an element satisfies the governing thin plate equation, substantially reducing the number of equations requiring generation and solution for the accurate analysis of beam-slab structures. Large elements corresponding to structural units bounded by beams may be used, requiring a minimum of data preparation. The examples considered show that engineering accuracy may be obtained with the generation and solution of very few equations. In addition, a modified version of the ACM element with conforming displacements is shown to be a sub-element of the proposed element. (Author abstract) 12 refs.

**080436 NEW SIMPLIFIED FINITE ELEMENT METHOD FOR ELASTIC-PLASTIC ANALYSIS OF PLATE BENDING PROBLEMS.** A new simplified finite element method for the elastic-plastic analysis of plate bending is developed from the general simplified method which the authors have proposed. Plastic nodal displacement increments of an element are derived from the yield condition as plastics potential expressed in terms of the nodal forces based on the flow rule of plasticity. Thus, the elastic-plastic stiffness matrix can be obtained without numerical integration over the domain of the element, unlike the conventional finite element method, once the elastic stiffness matrix is derived through either the displacement model or the assumed-stress hybrid model. Numerical solutions for the elastic-plastic bending problem of circular and rectangular plates demonstrates the efficiency and accuracy of the present finite element method compared with the conventional finite element method. (Edited author abstract) 17 refs.

**080437 MODIFIED SHAPE FUNCTIONS FOR THE THREE-NODE PLATE BENDING ELEMENT PASSING THE PATCH TEST.** A polynomial displacement basis for the three-node plate bending element (Zienkiewicz-triangle) is developed from a relaxed  $C^1$ -continuity requirement called the interpolation test. The test provides a general convergence criterion for non-conforming shape functions and a practical guideline to select a proper displacement basis. The resulting simple dis-

placement type element passes the patch test. Several reduced numerical integration schemes are discussed and numerical testing provides a comparisons with the standard element formulated by Zienkiewicz. (Author abstract) 9 refs.

**080438 TWO-DIMENSIONAL MODEL FOR CRACK CLOSURE EFFECT IN PLATES UNDER BENDING.** A two-dimensional model is proposed for taking into account the establishment of contact on the compression side of crack faces in plates under bending. An approximate but simple method is developed for evaluating reduction of stress intensity factor due to such 'crack closure'. Analysis is first carried out permitting interference of the crack faces. Contact forces are then introduced on the crack faces and their magnitudes determined from the consideration that the interference is just eliminated. The method is based partly on finite element analysis and partly on a continuum analysis using Irwin's solution for point loads on the crack line. (Author abstract) 23 refs.

**080440 INVESTIGATION OF BENDING OF STUDDED GASTIGHT PANELS.** In boiler construction there is a trend to create large equipment (operating on eastern brown coals) with a unit power of 500, 800, 1200, 2000 MW, widespread use of which in the future will offer the possibility of reducing capital costs and an almost twofold reduction in thermal power plant construction time, which is especially important for eastern regions of the country. Brown coals are characterized by a high ash content and, when burned, intense slagging of radiation and convective heating surfaces occurs. Studded membrane heating surfaces have become widespread in this connection in boilers that operate on eastern brown coals. In order to create a high-quality process and industrial equipment for manufacturing bent studded panels to the Scientific Production Association Atomkoltomash and the Production Association Krasnyi Kotel'shchik (Red Boilermaker) conducted experimental bending studies. 8 refs.

**080442 NOTE ON BENDING MOMENT DISTRIBUTIONS IN CANTILEVER PLATES IN FUNDAMENTAL MODE VIBRATION.** In an earlier paper, Dickinson and Di Blasio employed Gram-Schmidt polynomials in conjunction with the Rayleigh-Ritz method for conducting a free vibration analysis of rectangular plates. In particular, they extended their analysis of the cantilever plate to include the computation of bending moment and Kirchhoff shear force distributions. They made the correct observation that, unfortunately, there appeared to be no material published in the literature with which they could compare these latter results. The object of this brief note is to provide some results with which their data can be compared. 2 refs.

Gorman, D.J. (Univ of Ottawa, Ottawa, Ont, Can). *J Sound Vib* v 122 n 1 Apr 8 1988 p 185-187.

**080443 ANALYSIS OF SYMMETRIC CROSS-PLY LAMINATED ELASTIC PLATES USING A HIGHER-ORDER THEORY: PART I - STRESS AND DISPLACEMENT.** A simple theory for bending of composite anisotropic plates that are laminated symmetrically about their mid-plane is presented. This theory incorporates transverse shear deformation and transverse normal stress as well as the higher-order effects and fulfills the static conditions on the external boundary planes. Further on, by using Levy-type solutions considered in conjunction with the state space concept, the state of stress and displacement of rectangular plates for a variety of edge conditions is determined and the results are compared to their first-order shear deformation and classical counterparts, obtained by using the same state-space technique. (Author abstract) 11 refs.

**080449 ON THE VALIDITY OF THE REDUCED BENDING STIFFNESS METHOD FOR LAMINATED COMPOSITE PLATE ANALYSIS.** The 'reduced bending stiffness' (RBS) method has been used on occasions in the past as a means of simplifying the analysis of the flexural behavior of unsymmetrically laminated composite plates. However, the validity of the method has never been established. This paper makes direct comparisons between relatively simple, exact solutions for the static deflections, buckling loads and vibration frequencies of simply-supported plates and those arising from the RBS method. Extensive calculations are made for wide ranges of the physical parameters involved (aspect ratio, moduli ratio, lamination orientation angle, numbers of plies). The RBS method is found to yield sufficient accuracy for cross-ply plates. (Edited author abstract) 9 refs.

**080456 BOUNDARY CONDITIONS IN THE GENERALIZED THEORY OF PLATES.** Boundary conditions are considered only for the circular plates because the consideration for a plate with any form is too extensive to be quoted in this paper. But the way to find the boundary conditions for a plate with any form is similar to that for a circular plate. The results obtained with the equations presented in this paper for an actual example yield more information about the true stress-deformation state than the results which follow from classical theory. 1 ref.

**080457 NEW BOUNDARY ELEMENT METHOD FOR BENDING OF PLATES ON ELASTIC FOUNDATIONS.** The bending of plates on a Winkler foundation, according to Kirchhoff's theory, is solved by using an original boundary integral equation method involving the fundamental solution for plate flexure problems. An integral representation for the second member (pressure of the foundation) of the equation is given. By discretizing the integral equation, it is possible to eliminate the boundary unknowns, so that one is reduced to solving a linear system the solutions of which are deflections inside the domain. To illustrate the potentialities of this method several problems with various boundary conditions, loads and values of the modulus of the foundation are successfully solved. (Author abstract). 12 Refs.

**080458 THREE-DIMENSIONAL ELASTIC ANALYSIS OF CRACKED THICK PLATES UNDER BENDING FIELDS.** A three-dimensional analysis is presented for the bending problem of finite thick plates with through-the-thickness cracks. A general solution is obtained for Navier's equations of the theory of elasticity. It is found that the in-plane stresses and the transverse normal stress at the crack front are singular with an inverse square root singularity, while the transverse shear stresses are of the order of unity. Results from a numerical study indicate that the stress intensity factor, which varies across the thickness, is influenced by the thickness ratio in a significant manner. Results from a parametric study and those from a comparative study with existing finite element values are presented. (Author abstract). 23 Refs.

**080459 CONJECTURES RELATING TO RIGID-PLASTIC PLATE BENDING.** Rigid-plastic plate bending analysis has been studied for at least 40 years and many approximate solutions are available. There are, however, very few exact solutions known, even when the simplest yield criteria are employed. In order to focus attention on certain other aspects of these problems, some conjectures have been proposed. One of these conjectures is here considered further, and is applied to obtaining lower bound estimates for the collapse loads of clamped edge, regular shaped plates. (Author abstract). 7 Refs.

**080460 FIELD- AND EDGE-CONSISTENCY SYNTHESIS OF A 4-NODE QUADRILATERAL PLATE BENDING ELEMENT.** In this paper, we demonstrate the use of two conceptual principles, the field-consistency requirement and the edge-consistency requirement, as the basis for deriving a 4-noded quadrilateral plate bending element based on Mindlin plate theory using Jacobian transformations only. The derivation is now free of the use of such devices as strain-interpolation points and Hrennikoff strain reference lines, etc., which have been the basis for many recent formulations of this element. Numerical experiments show that this synthesis produces an element that should be identical to other recent formulations of this element based on tensorial transformations or on shear constraint condensation on the edges, but now given a more complete and formal logical basis. (Edited author abstract). 19 Refs.

**080461 PLATE BENDING ANALYSIS BY THE DUAL RECIPROCITY BOUNDARY ELEMENTS.** A new boundary element approach to the deflection analysis of thin elastic plates resting on Winkler-type elastic foundation is presented in this paper. Integral equations formulated using reciprocity theorem and conventional

fundamental solution to the biharmonic differential operator include domain integral relating to the reaction term of the original differential equation. The above-mentioned domain integrals are transformed into equivalent boundary integrals with further use of the reciprocity theorem. The transformed reaction is considered as an inhomogeneous term and a successive iteration scheme is employed for the solution of the integral equations. The effectiveness of the method is examined through some numerical examples for which analytical solutions are available. (Author abstract). 10 Refs.

**080462 FIELD-CONSISTENCY ANALYSIS OF THE ISOPARAMETRIC EIGHT-NODED PLATE BENDING ELEMENT.** This paper proceeds from the field-consistency paradigm to understand why the original element and even the element modified by the  $2 \times 2$  Gaussian rule cannot achieve consistently, the true shear strain constraints in the penalty limit of thin plate behaviour. It then derives the optimal shear strain definitions that leave the element free of all problems in the rectangular form, for most sets of practical boundary suppressions. From this, next is determined the optimum manner of co-ordinate transformation that preserves the true constraints even in the form of a general quadrilateral. This is achieved within the context of iso-P Jacobean transformations and without having to bring in tensorial or base vector definitions and transformations. This should be the simplest displacement type version of this element. (Edited author abstract). 29 refs.

**080463 ULTIMATE STRENGTH OF STEEL PLATES UNDER IN-PLANE BENDING AND COMPRESSION.** This paper presents the analytical results for the ultimate strength of steel plates under in-plane stress gradient based on the elasto-plastic finite displacement theory. Ultimate strength of steel plates and the effects of various parameters such as in-plane stress gradient, plate slenderness, aspect ratio, strain hardening of steel and initial imperfections are discussed analytically. Based on the analytical results, the ultimate strength formulas for uniform compression and for pure bending are proposed with good accuracy, and the interaction equation for the combined loading of compression and bending are also proposed in an exponential form. (Edited author abstract). 22 Refs.

**080464 HIGHER-ORDER THEORY OF HOMOGENEOUS PLATE FLEXURE.** The need for higher-order models to obtain accurate estimates to transverse shear and normal stresses and strains is well known. In this paper a higher-order shear deformation theory with provision for cubic variation of in-plane displacements and parabolic variation of the normal displacement has been considered for detailed study. Numerical results have been obtained for infinite plate strip, simply supported on opposite edges and infinitely long in the other direction, subjected to sinusoidal static load. Displacements, strains, and stresses are compared with the exact solution. Results by the classical plate theory, Levinson's theory and a higher-order theory based on partial deflections are also included. This study shows that the present model can predict all displacements, strains, and stresses reasonably accurately. Further, it is also noted that the statically equivalent estimates to transverse stresses from classical theory and the corresponding strains also agree closely with the exact solution. (Author abstract). 22 Refs.

**080465 BPM SOLUTION FOR ELLIPTIC PLATES SUBJECTED TO ECCENTRIC LOADS.** A high-

er-order boundary perturbation method (BPM), formulated to treat a class of problems defined in an elliptic domain, is developed to obtain the Green's function due to an eccentric source. The method, based on a dual perturbation, leads to expansion solutions expressed in terms of ellipticity and eccentricity perturbation parameters. General explicit expressions for equivalent boundary conditions on the perturbed boundary are first derived to treat the class of problems for which the associated boundary conditions are of the Dirichlet or Neumann type. The BPM is applied to investigate a clamped elliptic plate subject to eccentric loads. (Edited author abstract). 7 Refs.

**080466 BENDING OF RECTANGULAR PLATES WITH VARIABLE RIGIDITIES.** A microcomputer-oriented semianalytical method of solution is presented for rectangular plates with variable rigidity or thickness. The solution procedure is based on the classical method of separation of variables. The two-dimensional governing partial differential equation is first reduced to an ordinary differential equation. The classical unidirectional finite-difference method is then employed to solve the resulting ordinary differential equation. Results are presented for plates with different edge and loading conditions. Results for partially loaded plates with variable rigidity or thickness are presented in the literature for the first time. (Author abstract). 12 Refs.

**080467 BOUNDARY ELEMENT BENDING ANALYSIS OF MODERATELY THICK PLATES.** In this paper the boundary element method is applied to analyze homogeneous isotropic plates in bending using Reissner's theory. This formulation involves three coupled integral equations and can be applied not only to moderately thick plates, but also to some usually analyzed by classical Kirchhoff-Love thin plate theory. It is shown that the boundary element method gives accurate results and can be applied to cases when traction discontinuity may occur or even in the presence of singularities, using double nodes or simple discontinuous elements. Numerical results are compared against analytical or finite element solutions to illustrate the accuracy of the boundary element formulation. (Edited author abstract). 17 Refs.

**080468 RECTANGULAR FINITE ELEMENT FOR ANALYSIS OF THICK PLATE BENDING.** The explicit form of the  $12 \times 12$  stiffness matrix of a rectangular element for analysis of thick plate bending is presented. The element is assembled from six uni-dimensional prismatic bars, and the elemental stiffness properties, are obtained through the framework concept originated by A. Hrennikoff. The shear deformations of all the bars, comprising the rectangular lattice model, are taken into account, so that rigorous analysis of thick plate bending becomes possible. The influence of shear deformations, and the effects of plate thickness, on the deflections and bending moments of a rectangular plate, are illustrated by a numerical example. (Edited author abstract). 24 Refs.

## Blasting

**080469 BEHAVIOUR OF LAMINATED PLATES SUBJECTED TO CONVENTIONAL BLAST.** Response of simply supported anti-symmetrically laminated angle-ply plates to explosive blast loading is considered. A closed-form solution is obtained for thick plates, it being assumed that the material remains in the elastic range. The effect of transverse shear deformations on the response of thick plates is taken into consideration. The behaviour of thin laminated plates subjected to blast is studied using

geometrically non-linear theory. Initial imperfections, which can be important for thin plates, are included in the analysis. The solution for thin elastic laminated plates is obtained numerically using a Runge-Kutta method. The analysis yields the non-dimensional deflection vs time relationship which can be used to determine the stresses and strains in the layers of the plate. (Author abstract) 22 refs.

**080471 CURVATURE EFFECTS IN THE BUCKLING OF SYMMETRICALLY-LAMINATED RECTANGULAR PLATES WITH TRANSVERSE SHEAR DEFORMATION.** It is shown that the effect of stress discontinuities from ply-to-ply must be taken into account when curvature terms are included along with shear deformation in the buckling analysis of rectangular, symmetrically-laminated plates. Such ply-stress discontinuities lead to curvature terms in the governing equations which differ considerably from those derived for homogeneous plates. Critical buckling loads are determined for orthotropic laminates subjected to biaxial inplane loading and for cylindrical bending of anisotropic plates subjected to uniaxial compression loading. Simply-supported boundary conditions are considered in conjunction with the rectangular, orthotropic laminate, while simply-supported and clamped boundaries are considered for the case of cylindrical bending of anisotropic plates. **080475 BUCKLING, POSTBUCKLING, AND NONLINEAR VIBRATIONS OF IMPERFECT PLATES.** Formulations and computational procedures are presented for studying the geometrically nonlinear behavior, including buckling, postbuckling, and nonlinear vibrations of perfect and imperfect, isotropic and laminated thin plates. The finite-element method is used. The element used is a 48 degree-of-freedom thin flat plate rectangular element capable of modeling arbitrary imperfections. The incremental and total stiffness matrices for large displacement behavior are derived based on the total Lagrangian approach in conjunction with the Hamilton's principle. The geometric imperfections are treated by considering additional terms in the strain-displacement relations. Numerical results are presented for a variety of examples. **080476 POST-BUCKLING RESPONSE OF ISOTROPIC AND LAMINATED COMPOSITE SQUARE PLATES WITH CIRCULAR HOLES.** In this paper, the authors emphasize the well-known anomalous behavior observed in buckling of square plates with centrally located cut-outs. For certain size holes and depending upon whether the loading is displacement or stress controlled, perforated square plates have higher buckling loads than equivalent solid plates. Because of this anomaly, the authors have examined the post-buckling response of such plates of both isotropic and laminated composite construction. Having concluded from their post-buckling response that such plates are imperfection-insensitive except for a slight loss of their post-buckling strength resulting from the presence of the hole, the authors go on to examine the possible weight savings in using perforated square plates to resist buckling. **080478 BEYOND BUCKLING A NONLINEAR FE ANALYSIS.** For some time now, engineers have been using linear finite element analysis to determine the point of instability, or bifurcation, in buckling problems. Although linear methods often do a good job of estimating the load under which a structure buckles, they do not provide information about what happens after buckling. Neither can they account for potential nonlinearities that may have significant effects on the collapse load. In contrast, nonlinear analysis can now provide the means to follow the displacement history of a buckling structure up to the point of collapse and beyond. The paper discusses the use of Nonlinear finite element analysis for the solution of post-buckling behavior of structures.

**080480 VIBRATION AND POST-BUCKLING OF GEOMETRICALLY IMPERFECT, SIMPLY SUPPORTED, RECTANGULAR PLATES UNDER UNI-AXIAL LOADING, PART I: THEORETICAL APPROACH.** The work described in this paper constitutes the theoretical part of a theoretical and experimental study of the post-buckling and vibration of simply supported rectangular plates having slight initial curvature (geometrical imperfection) and subject to uni-axially applied, in-plane, compressive loads. The experimental part, and the comparison with theoretical predictions, is given in a second paper. The results presented appear to suggest that an approximately linear relationship exist between a load-frequency parameter and the central deflection of the plates considered, for a substantial in-plane loading range. (Edited author abstract) 25 refs.

Ilanko, S. (Univ of Western Ontario, London, Ont, Can); Dickinson, S.M. *J Sound Vib* v 118 n 2 Oct 22 1987 p 313-336.

**080481 VIBRATION AND POST-BUCKLING OF GEOMETRICALLY IMPERFECT, SIMPLY SUPPORTED, RECTANGULAR PLATES UNDER UNI-AXIAL LOADING, PART II: EXPERIMENTAL INVESTIGATION.** The paper describes the experimental part of a theoretical and experimental study of the post-buckling and free vibrational behavior of thin, rectangular, simply supported plates having initial geometrical imperfection and subject to uni-axially applied, in-plane, compressive loads. The experimental apparatus and procedure used are described. The fundamental natural frequency and central deflection of several plates of different thickness and degree of initial imperfection, subject to loads varying from zero to several times the critical buckling value, are compared with values predicted by using the Rayleigh-Ritz solution described in the companion paper. For one plate, comparisons of theoretically predicted and experimentally measured strains are given. Close agreement is shown to exist between the theoretical and experimental results. An

approximate linear relationship between a load-frequency parameter and the central deflection, discussed in the theoretical study, is also shown to exist for the experimental plates. (Author abstract) 11 refs.

**080486 BUCKLING AND BENDING BEHAVIOUR OF INITIALLY STRESSED SPECIALLY ORTHOTROPIC THICK PLATES.** The virtual work theorem is employed to derive the governing equations of specially orthotropic plates in a general state of non-uniform initial stress, where the effects of transverse shear are included. The equations were adjusted to a generic form by using appropriate transformations. Considering the transformations, introducing generalized parameters and employing a similarity parameter, comprehensive solutions are found to this problem; hence, the curves presented in the text are generic rather than specific. The thick plate equations are solved for a simply-supported rectangular specially orthotropic plate in a state of combined uniform uniaxial compression and bending. The results of the reduced set of equations agree with those obtained by previous investigators. (Author abstract)

**080488 POST-BUCKLING BEHAVIOR OF CENTRALLY CRACKED PLATES UNDER TENSION.** The post-buckling behavior of centrally cracked rectangular plates subjected to a uniaxial tension is analyzed by the finite element method, taking into account both geometrical and material nonlinearities. The finite element formulation is based on the total Lagrangian coordinate system and the flow theory of plasticity. The effects of an initial imperfection on buckling deformation are studied in some detail. Post-buckling behavior is discussed in relation to undesirable effects on the fracture of cracked plates. The results of elastic analyses show that the magnitude of the stress intensity factor increases after buckling. The results of elastic-plastic analyses and experiments show that the residual strength of cracked plates is reduced by the interaction between buckling deformation and plastic deformation at the ends of cracks. (Author abstract) 23 refs.

**080489 ELASTIC BUCKLING AND FLEXURAL VIBRATION OF VARIABLE-THICKNESS ANNULAR PLATES UNDER NONUNIFORM IN-PLANE FORCES.** This paper deals with elastic buckling and flexural vibration of annular plates whose thickness vary linearly in the radial direction. The annular plate is subjected to in-plane forces along its inner and outer edges, which vary in the circumferential direction. These problems are analyzed by the Galerkin method. Eigenfunctions of the natural vibration of a constant-thickness annular plate without in-plane forces are used as admissible functions. Two types of in-plane forces are adopted; one a sinusoidally varying nonuniformity along the outer edge, and the other uniform along parts of the outer edge and zero on the remainder of the edge. The influences of the nonuniformity of the in-plane forces on the buckling load and natural frequencies are investigated. It is found that the increase of the nonuniformity decreases the buckling load and the fundamental natural frequency. This tendency becomes more evident when the thickness of the plate at the inner edge is thinner and the hole larger. (Author abstract) 10 refs.

**080492 BUCKLING OF A BIMODULUS THICK RECTANGULAR PLATE BASED ON HIGHER-ORDER PLATE THEORY.** This paper presents the governing equations of a simply supported rectangular bimodulus thick plate related to the higher order shear deformation terms. The buckling coefficients obtained by the iteration method are compared with the former results for ordinary thick plates. The Mindlin plate theory result can be obtained by simplifying the governing equation of the higher-order plate theory formulation. The effects of higher-order shear deformation terms on the neutral surface locations and the buckling coefficients are evaluated by observing the difference between present higher-order theory results and Mindlin plate theory results. Also, the bending stress is shown to reduce the buckling coefficient significantly. (Author abstract) 28 refs.

**080494 COMPOUND STRIP METHOD FOR THE BUCKLING ANALYSIS OF CONTINUOUS PLATES.** A special finite strip method is developed for the analysis of linear buckling of flat plate systems that are continuous over non-rigid supports. This approach incorporates the effect of support elements in a direct stiffness methodology. The stiffness contribution of the support elements adds directly to the plate strip stiffness matrices at the element level prior to assembly. This summation of plate and support stiffness contributions forms a substructure, which is termed a compound strip. The compound strip methodology may be readily employed for the enhancement of computer programs based on traditional finite strip procedures. The validity of the compound strip method for elastic buckling analysis is demonstrated in two examples. The critical loads based on compound strip

methodology compare favorably with those obtained with the finite element method. (Author abstract) 42 refs.

**080495 THERMAL POST-BUCKLING OF A SQUARE PLATE RESTING ON AN ELASTIC FOUNDATION BY FINITE ELEMENT METHOD.** A simple finite element formulation is presented for evaluating the thermal post-buckling behavior of rectangular plates. The results are presented in the form of linear thermal loads and ratios of nonlinear to linear thermal loads for various values of the central deflection and for three sets of boundary conditions. The effect of elastic foundation on the thermal post-buckling behavior is also evaluated for various of foundation stiffness parameter. (Author abstract) 8 refs.

**080496 RADIALLY COMPRESSED LAMINATED CIRCULAR PLATES.** The paper deals with buckling of complete and annular circular plates, made of symmetric laminates with general orientation of the lamina fibers. The plate is subjected to an in-plane, symmetric, destabilizing load. The load is applied at the outer edge for the complete plate and at the outer and inner edges for the annular one. The plate is supported in various ways along its boundaries. The paper includes the derivation of the governing equations and discusses the various methods of solution. Numerical results are presented for a clamped plate. (Author abstract) 14 refs.

**080497 DYNAMIC BEHAVIOUR OF POSTBUCKLED COMPOSITE PLATES UNDER ACOUSTIC EXCITATION.** The Rayleigh-Ritz method was used to find the postbuckling static displacement pattern of a composite plate (CFRP) under uniaxial in-plane compression of uniform edge-shortening. The resonance frequencies and mode shapes at various postbuckled states are then evaluated by eigenvalue analysis of the dynamic matrix equation consisting of up-dated tangential stiffness matrix at corresponding static configuration. The theoretical results are compared with experimental results obtained in 16-layered CFRP laminate of aspect ratio 1.5. The resonance frequencies and mode shapes obtained are used to interpret the multimodal and nonlinear strain responses to high level of acoustic excitation. The dominance of second-mode contribution and softening-spring behavior are found in the strain response of postbuckled plates. (Author abstract) 9 refs.

**080498 OPTIMAL FIBRE ORIENTATION FOR SIMPLY-SUPPORTED, ANGLE-PLY PLATES UNDER BIAXIAL COMPRESSION.** Optimum laminate configurations for laminated rectangular plates under uniaxial or biaxial compression are investigated and are obtained under buckling constraints. Complete freedom is permitted in the selection of the ply angle variation through the thickness; however, it is proved that the maximum buckling load occurs when the orientation angle in each of the layers is the same. Three types of optimal angle (direction) are obtained in terms of the material properties, the geometrical properties and the type of buckling mode. They are expressed in closed analytical form. (Author abstract) 10 refs.

**080500 MAGNETOELASTIC BUCKLING: WHY THEORY AND EXPERIMENT DISAGREE.** In 1968, F.C. Moon and Y.W. Pao presented a theory of the magnetoelastic buckling of a beam plate in a uniform magnetic field which differed from experimental results by a factor of two. It is shown that the assumption made by Moon and Pao - that a plate element experiences a force system consisting only of a couple, whose magnitude is proportional to the rotation of the element - is invalid for finite plates. An experiment is suggested for determining whether the assumption is valid for infinite plates. The present state of knowledge concerning magnetoelastic buckling is briefly summarized. Several types of magnetoelastic buckling are identified and briefly contrasted. Attention is directed to the importance of field discontinuities in problems involving magnetic deformation. Two paradoxical aspects of the Moon-Pao formula for the magnetoelastic buckling of beam plates are pointed out and briefly discussed. (Edited author abstract) 15 refs.

**080503 EVALUATION OF ULTIMATE STRENGTH OF STEEL PLATES WITH INITIAL IMPERFECTIONS UNDER IN-PLANE BENDING AND COMPRESSION.** There are few studies on the ultimate strength of steel plates under in-plane combined loading, and their basic strength curves in the design specifications in many countries are still based on the elastic buckling theory using relevant safety factors. Evaluation in the ultimate strength is essential to promote the ultimate limit-state design method. This paper presents the ultimate strength of plate panel under in-plane stress gradient. Based on the analytical results, the ultimate strength formulas for uniform compress and pure bending are proposed respectively, and the interaction

formula for the combined loading of compression and bending are then proposed. (Author abstract) In Japanese. 15 refs.

**080507 BUCKLING OF RING-STIFFENED MULTI-ANNULAR PLATES.** The buckling of multi-annular plates stiffened by rings at the common joints and loaded by in-plane symmetric forces is investigated. The plate considered is simply-supported or clamped at the outer boundary. The various annular sections are homogeneous, monolithically connected through rings, without eccentricity, and differ either in geometry or in material properties, or both. The effect of the ring extensional (in-plane) rigidity is considered, in addition to the effect of the ring flexural and torsional rigidities. These effects are substantiated through parametric studies. The presented numerical examples consist of annular plates with one or two annular sections reinforced by a single ring. (Author abstract) 12 refs.

**080510 ELASTIC-PLASTIC SNAPPING-THROUGH OF A CURVED METAL STRIP COMPRESSED BETWEEN TWO RIGID PLATES (2ND REPORT, THE INFLUENCE OF THE SUPPORTED END CONDITION ON THE SNAP-THROUGH).** The quasi-static loading on a curved strip compressed by a flat, rigid plate is considered with particular reference to large deformations, the ensuring buckling behavior and the effect of the supported end condition on the snap-through. The deformation characteristics have been analyzed using an incremental finite element technique. Particular attention has been paid to modeling the situation when a node contacts the plate, and to the condition for separation of the strip from the plate. It was found that the normalized force of the clamped ends of the shell was larger than that of the pinned ends at snapping point and that the amount of plate displacement and the distance of the clamped edges of the shell between the contact point in at the central point were smaller than those of the pinned edges at snapping point. (Author abstract). 16 Refs. In Japanese.

**080514 ON THE GLOBAL LARGE DEFLECTION AND POSTBUCKLING OF SYMMETRIC ANGLE-PLY LAMINATED PLATES.** This paper presents studies of the global nonlinear deflection and postbuckling behavior of symmetric angle-ply laminated plates. A new transformation between on-axis and off-axis modulus is established to make a link between the stiffness of angle-ply plates and the global constants in orthotropic transformed space. All the linear and nonlinear terms in the plate equations are properly nondimensionalized, such that the results in this paper are generic rather than specific. The results indicate that with increasing generalized rigidity ratio  $D^*$ , the deflection is reduced and the buckling coefficient is increased, and naturally the post-buckling deflection is decreased. The generalized Poisson's ratio only has a small effect on the problems. The information presented in the text should be helpful to whoever is seeking a better understanding of the correlation between composite material properties and nonlinear behavior of laminated plates. (Author abstract). 17 Refs.

**080515 COMPARISON OF THE POSTBUCKLING BEHAVIOR OF PLATES AND SHELLS.** There is a basic difference in the mathematical treatment of post-buckling of plates and shells. Whereas for plates the classical methods of bifurcation theory (Lyapunov-Schmidt method, Singularity Theory) in general are applicable, these methods fail for the analysis of thin-walled shells. For shells in general solutions of the boundary layer type are found and hence the methods of singular perturbation theory are required for an appropriate analysis. Applications are given for the postbuckling of a rectangular plate and a spherical shell. (Author abstract) 17 refs.

## Calculations

**080516 NEKONECNA ZALUZIOVA DOSKA NA PRUZNOM PODLOZI, NAMAHANA SPOJITYMI USEKOVYMI A SUSTREDENYMI KRUTIACIMI MOMENTMI.** [Infinite Louver Type Plate Resting on Elastic Foundation Loaded with Continuous Interval and Concentrated Twisting Moments]. The paper deals with bending and twisting of infinite louver type plates resting on elastic foundation loaded in a finite interval with continuously distributed moments  $m$  and concentrated twisting moments  $K$ . The author presupposes that louver type plates consist of  $n+1$ , parallel spaced with longitudinal hinges mutually connected beams resting on the Winkler type foundation which resists against bending and twisting of individual beams. Deformation of such a plate is described by  $n$  differential equations of 4th order for transformed functions of bending as well as by  $n+1$  differential equations of 2nd order for transformed functions of twisting angles of individual beams constituting the plate. (Edited author abstract) In Slovak. 4 refs.

**080522 LIMITING THE SIZE OF COMPOSITE OPTIMIZATION PROBLEMS.** It is shown that an optimal composite structure can be obtained using a maximum of  $12N$  design variables, where  $N$  is the number of plate, membrane and end-load elements used to model the structure. This upper bound allows for variation of layer thickness and orientation and is independent of the complexity of the finite elements used and the number of load cases considered. Classical lamination theory and the equilibrium equations for each element are used to derive the upper bound which results in it also being independent of the number and form of deflection and stress constraints, with the only proviso being that the latter must be compatible with lamination theory. (Author abstract) 9 refs.

Watkins, R.I. (CSIR, Pretoria, S Afr). *Comput Struct* v 28 n 2 1988 p 237-240.

**080523 ANALYSIS OF INTERLAMINAR STRESSES NEAR CURVED FREE-EDGES OF LAMINATED COMPOSITES USING ITERATIVE FINITE ELEMENT METHOD.** In this paper, a three-dimensional iterative finite element method is applied to analyze the stress distribution near the free edge of a circular cut-out of finite laminated composite plates under biaxial loading. This finite element program is developed from a continuous nodal mixed field. The iterative procedure is very effective. Accurate numerical results normally can be obtained with only five iterations and relatively coarse meshes. Numerical results of interlaminar shear stress and hoop stress near a circular free edge are obtained under various loading cases by changing the ratio of the applied biaxial stresses. The effects of using adhesive layers (soft layers) on the stress distribution near the free edges of a free-curved boundary are also investigated. It is observed that, in general, the adhesive layers will reduce the magnitude of the interlaminar shear stress. (Edited author abstract) 18 refs.

**080527 COMPARATIVE STUDY ON DIFFERENT LAYERED COMPOSITE PLATE THEORIES.** In recent years a considerable number of higher order theories for the analysis of layered composite plate was published. In order to gain information about their accuracy and efficiency, an exact solution for simply supported rectangular plates laid in 0° and 90° direction is set up within the scope of the three-dimensional elasticity theory. This serves as a standard of comparison for eight different plate theories. It turns out that applying these higher order theories is sensible only within a limited slenderness region, where the theories of Murthy (1981) and Reddy (1984) have proved themselves to be most effective. They show drawbacks, however, for the development of finite elements; Mindlin's theory (1951) is better suited for that purpose, provided that improved transverse shear stiffnesses are applied. (Edited author abstract) 21 Refs.

## Computer Aided Analysis

**080528 ANALYTICAL MODELING OF PRECURSOR DECAY IN STRAIN-RATE DEPENDENT MATERIALS.** A finite difference computer code is used to numerically simulate uniaxial strain waves generated from plate impact experiments. The incremental flow law of Bodner and Parton is used to describe the strain rate dependent plastic flow in 7039 aluminum and C1008 steel. Constants determined from Hopkinson bar tests and plate impact experiments are found adequate to predict precursor decay in these materials. A mathematical definition of the Hugoniot elastic limit (HEL) based on a plastic strain offset criterion is proposed. (Author abstract) 16 refs.

Nicholas, Theodore (Univ of Dayton, Dayton, OH, USA); Rajendran, A.M.; Grove, David J. *Int J Solids Struct* v 23 n 12 1987 p 1601-1614.

**080529 FINITE DIFFERENCE SOLUTION FOR PLATE ON ELASTIC SOLID.** A new adaptation of an existing finite difference solution to the problem of a plate resting on an elastic solid foundation is introduced (program FIDIES). Square elements are employed throughout the slab, and external distributed loads are converted to point forces applied at the center of corresponding grid squares. The accuracy of FIDIES is confirmed by comparison with closed-form solutions, when available, an earlier finite difference solution, as well as these convergence studies. The effect of slab size is investigated for each of the three fundamental loading conditions, i.e., interior, edge, and corner. Predictive equations are derived for the latter two cases. These formulas, which were previously unavailable, highlight differences in behavior exhibited by the elastic solid and dense liquid subgrade idealization. (Edited author abstract) 13 refs.

## Computer Simulation

**080530 SEMI-LOOF SHELL, PLATE AND BEAM ELEMENTS - NEW COMPUTER VERSIONS: PART 1. ELEMENTS FORMULATION.** The semi-loof ele-

ment is one of the most efficient for the solution of thin shells of arbitrary geometry. Originally published by B.M. Irons it has been the object of much research with respect to its philosophy and performance in various structural situations. The original program is an intricate and hard to understand piece of programming. It is also very difficult to introduce changes in the program as the various steps involved are not well individualized. The new code possesses some advantages: the element program results are easier and more clear; it is easier to detect errors and introduce modifications; it is easier to delete parts of the program that may not be relevant for every particular case study; it is possible to derive simpler elements to be used in the analysis of particular types of structures. These arrays for the shell, plate and beam elements are denoted respectively by WSHEL, WPLAT and WBEAM. 10 refs.

Martins, R.A.F. (Univ of Oporto, Porto, Port); Oliveira, C.A.M. *Eng Comput (Swansea Wales)* v 5 n 1 Mar 1988 p 15-25.

**080531 SEMI-LOOF SHELL, PLATE AND BEAM ELEMENTS - NEW COMPUTER VERSIONS: PART 2. ELEMENTS PROGRAMMING.** Semi-loof shell, plate and beam elements are implemented in such a way that three independent blocks are formed to obtain the stiffness, mass, load and stress matrices. These three blocks are controlled by subroutine MSTIF, which is directly called from a standard FE program. Subroutine MSTIF is the main program for SHELSTIF, PLSTIF and BEAMSTIF. These 3 subroutines correspond to the shell, plate and beam elements, respectively. MSTIF selects which block of subroutines must be called for each element.

Martins, R.A.F. (Univ of Oporto, Porto, Port); Oliveira, C.A.M. *Eng Comput (Swansea Wales)* v 5 n 1 Mar 1988 p 26-38.

## Concrete

**080532 FAILURE MECHANISMS IN R/C PLATES CARRYING IN-PLANE FORCES.** Failures due to the yielding of reinforcement and due to the crushing of concrete are examined. In the case of yielding of steel, equations are derived which predict the ultimate load and the direction of the ultimate crack for proportional loading. In the case of crushing of concrete, the tensor of concrete stresses between the crack is derived, and the ultimate load is determined from the concrete strength under combined tension and compression. The ultimate load is predicted for both proportional and nonproportional loading. Derived equations have been applied to plate elements reinforced with steel bars in two orthogonal directions, and subjected to uniaxial or biaxial uniform loading. (Edited author abstract) 21 refs.

**080535 STABILITY OF CONCRETE PLATES.** Concrete plates supported along all edges are commonly used as structural elements in the hulls of concrete floating structures such as concrete ships, barges, pontoons, floating ports and bridges where they are subjected to combined compressive in-plane and lateral loads. Several analytical methods exist and test results are available for concrete plates under pure in-plane or pure lateral loads. A method of analysis is developed here based on the assumed deflection method. In this way calculation of the strength of a plate is reduced to a one-degree of freedom problem. A design method similar to the moment magnifier approach for slender columns is also developed based on a Fourier series expression of the deflection and lateral load. Nine reinforced concrete plate specimens were tested under in-plane and lateral loads. (Edited author abstract) 112 refs.

**080537 CRACK KINKING IN ANTI-PLANE SHEAR SOLVED BY THE MELLIN TRANSFORM.** The problem of kinking of internal cracks in infinite plates submitted to antiplane shear at infinity was solved by using the Mellin transform. This transform allows a straightforward reduction of it to a system of second order Fredholm integral equations for a pair of functions in terms of which the stress intensity factors at the crack tips may be calculated. Of great interest and of equivocal views is the regime at the vicinity of the corner, the region where the kink is nucleated, and which reflects numerical difficulties arising in the solution of the integral equations. For this purpose an asymptotic expansion is constructed for their kernels and subsequently for the values of SIFs with respect to the length  $\epsilon$  of the kinked branch. The results were in agreement with those obtained for an in-plane loading of the cracks and for cracks in bi-phase materials whose tips are on the interface of the phases. (Edited author abstract) 20 refs.

**080538 STRESSED STATE OF POLYGONAL PLATE WITH CENTRAL CIRCULAR HOLLOW AND TWO LINEAR CRACKS.** This paper considers a homogeneous isotropic plate filling a doubly connected region, limited internally by the central circle and two linear cracks, and externally by a regular curvilinear polygon. In solving the problems of the elasticity theory for general case of three-dimensional media we encounter great mathematical difficulties. This circumstance leads us to seek the effective methods of solving wide classes of

particular cases of practical significance, the plane problem of the elasticity theory being one of the most important classes of such a type. It is known that the solution of the problems in plane elasticity theory is essentially simplified if one neglects the mass forces remembering that the problem with the mass forces can always be reduced to the problem without the mass forces to find any particular solution of the respective inhomogeneous differential equations. 12 refs.

**080539 NUMERICAL STUDY OF THE TRANSIENT BEHAVIOR OF AN INTERFACIAL CRACK IN A BIMATERIAL PLATE.** In this paper we developed a numerical method to determine the transient stress intensity factor and crack opening displacement of an interfacial stationary crack in a bimaterial plate subjected to time dependent anti-plane shear stress on the surfaces of the plate. A bimaterial plate of finite length of dissimilar elastic, isotropic laminae with Griffith type of crack at the interface is analyzed. For the numerical method the finite element equations are derived in the frequency domain from a variational principle. The stress intensity factors in the frequency domain are evaluated from the displacements, which are obtained upon solving the finite element equations. The transient stress intensity factor is then obtained by numerical Fourier inversion technique using the Fast Fourier Transform (FFT) routine. Quarter point elements and transition elements are used to model the crack tip singularity. (Edited author abstract) 20 refs.

**080540 PATH-INDEPENDENT LINE INTEGRALS FOR STEADY-STATE, TWO-DIMENSIONAL THERMOELASTICITY.** Three path-independent line integrals  $J_k$ ,  $M'$ , and  $L_3$  are derived for steady-state, two-dimensional thermoelasticity. These integrals are similar to the  $J_k$ ,  $M$ , and  $L_3$  presented by Knowles and Sternberg, but include additional terms of either free expansion displacement vector  $u_k$  or temperature  $\theta$  and its conjugate harmonic function  $\Omega$  in their formulation. These new line integrals enable us to avoid the undesirable area integration when calculating the strain energy release rate for crack problems. Application of  $J$  and  $L_3$  is demonstrated through a sample problem of a constant heat flux disturbed by a finite crack in an infinite plate. (Edited author abstract) 14 refs.

**080541 GENERAL SOLUTION OF A CENTRAL CRACK OFF THE CENTER LINE OF A RECTANGULAR SHEET FOR MODE III.** The purpose of this study is to use the basic theorem of the Fourier transform and Fourier series to find the general solution of the stress intensity factor of a central crack off the centre line of a rectangular sheet subjected to an arbitrary anti-plane shear. The result of the mixed boundary value problem may be expressed in terms of a Fredholm integral equation or by a particular series. It is easy to prove that the solution of a central crack off the center line of a strip and that the result of a central crack coincident with the centre line of a rectangular sheet of the mode II are the special cases of the general solution in this article. (Author abstract) 12 refs.

**080542 MIXED-MODE CRACK GROWTH PREDICTIONS.** The problem of slow stable growth of an inclined crack in a plate subjected to uniaxial tension is studied by the strain energy density criterion. The stable crack growth process is simulated by predicting a series of crack growth steps corresponding to a piecewise loading increase when material elements along the direction of crack extension absorb a critical amount of elastic strain energy density. Crack instability takes place when the last

ligament of crack extension takes a critical value which is a material constant. The critical stress at the onset of crack initiation and unstable crack extension is determined for various crack inclination angles. Three different loading step increments corresponding to three different loading rates are considered and their effect on stable crack growth is analysed. (Edited author abstract) 18 refs.

**080543 ON THE EQUIVALENT ORDER OF CRACK-TIP SINGULARITY DEFINED BY CAUSTICS.** The problem of a transverse Griffith crack in an infinite plate submitted to simple tension at infinity was studied by using its closed form solution described by the elastic potential function  $\phi(z)$ . The exact form of the caustic and its generatrix curve formed around the crack tips was exactly described by using the  $\phi(z)$ -function. These exact forms were compared with the respective forms given either by the singular one-term solution of the problem and accepting that the order of singularity at the crack tip is  $(1/2)$ , or by a solution defining the order of singularity and the respective stress intensity factor by taking into consideration the influence of the distance from the crack tip where these quantities are evaluated. It was shown by comparing the first stress invariant  $I_1$ , whose gradient defines the respective caustic, that the differences between the exact values and the values of  $I_1$  derived by the proposed method with variable order of singularity is much smaller than the differences between the exact solution and the singular solution. **080544 DYNAMIC INTERACTION BETWEEN TWO INTERFACE CRACKS IN A THREE-LAYERED PLATE.** In this paper, the dynamic interaction between two interface cracks, in a three-layered plate subjected to antiplane stress fields, is analytically studied. The problem is formulated in terms of a coupled set of integral equations, which are then solved by expanding the unknown crack opening displacements in a complete set of Chebyshev polynomials. The method is coded in a FORTRAN program and numerical results for a sample problem are presented. The results show that for the problem studied here one crack always reduces the crack opening displacements of its neighboring crack. (Author abstract) 12 refs.

**080545 THICKNESS CRITERION FOR FRACTURE TOUGHNESS TESTING BASED ON A PLANE STRESS COMPATIBLE SOLUTION.** In this paper, an elastic compatible plane stress solution for a thin plate with an elliptic hole or a crack is obtained by a complex variable method. The result is used to study the stress field near tensile crack-tips. It is shown that the effect of incompatibility of conventional plane stress solutions on the stress distribution near the crack tips may not be ignored. A model for the study of the thickness effect of fracture toughness in plane stress states is then proposed. Comparisons of this model with available experimental data and other models are also presented. (Author abstract) 8 refs.

**080547 GENERAL SOLUTIONS OF AN INFINITE SHEET WITH DOUBLY PERIODIC CRACKS MOVING AT CONSTANT VELOCITY.** In accordance with two different methods, we shall first prove that the dynamic stress intensity factor of mode I of an infinite sheet with a central crack propagation at constant velocity is independent of material constants and the uniform velocity. Then, we may give the general solutions to the more complicated problems of an infinite plate weakened by an infinite series of doubly periodic cracks moving at constant velocity under concentrated forces  $P$  and  $Q$  in this paper. Of course, the dynamic stress intensity factors of them are also independent of material constants and the uniform velocity. (Edited author abstract) 8 refs.

**080548 STRESS FUNCTIONS WITH FINITE STRESS CONCENTRATIONS AT THE CRACK TIPS FOR A CENTRAL CRACKED PANEL.** In this paper a plate with a central crack in uniform tension or shear is analyzed. A method is presented of forming the transition interval at the crack tip where both the crack opening displacement and the finite stress concentrations appears. The problems are solved using the weight integral method. The stress functions of this type are more suitable than Westergaard's function or Dugdale's assumption to analyze the crack problems contained in materials such as concrete or rock. The results of several possible stress distributions, the crack opening displacement shapes and the  $J$ -integrals are revealed in the numerical examples. (Author abstract) 18 refs.

**080549 ABOUT THE DUGDALE CRACK UNDER MIXED MODE LOADING.** A crack in an infinite plate is considered from a viewpoint of pure elasticity theory. The plane problem of a Dugdale crack under mixed mode loading is investigated. An exact closed form solution is given and the corresponding crack displacements are discussed. It is proposed to interrelate the tensile and shear strip yield stresses of the Dugdale model to the v. Mises equivalent stress. (Edited author abstract) 9 refs.

**080550 ELASTIC OVERLAPPING OF THE CRACK FLANKS UNDER MIXED-MODE LOADING.** The properties of an inclined Griffith crack in an infinite elastic plate submitted to a biaxial loading at infinity, due to the deformation of the crack flanks according to the one-term approximation, usually applied in linear elastic fracture mechanics, and the two-term approximation, were compared with the respective properties developed according to the exact solution. It has been shown that there are significant differences between the exact and the approximate solutions. Thus the one-term approximation, the so-called 'singular solution', predicts immovable crack tips, no angular displacement of the deformed crack flanks and therefore is in general inadequate for the accurate description of the mixed-mode deformed crack, and which therefore cannot be made only in terms of the two components of the stress intensity factor. The mode of displacement of the crack flanks creates their eventual overlapping, depending on the relationship between normal and shear loading of the plate. This overlapping phenomenon was systematically investigated. Mode-II deformation always develops overlapping of the crack flanks, thus violating the initial boundary values of the pose problem, and therefore

necessitates a different mode of attack and a realistic consideration of the initial boundary conditions. (Edited author abstract). 18 Refs.

**080551 EFFECTIVE NUMERICAL STRESS INTENSITY FACTOR CALCULATION WITH NO CRACK DISCRETIZATION.** An effective numerical procedure for calculating stress intensity factors (SIF) in plane problems based on a modified boundary element technique not requiring any crack discretization was proposed by Snyder. Instead of the usual fundamental solution, he used Green's function for the problem of a traction-free central crack in an anisotropic plate. In the first part of the present paper, the corresponding Green's function for the isotropic problem is presented. In addition to the central crack, a semi-infinite edge crack is considered. Both Green's functions are given for the case of the anti-plane state strain as well. In the first step of the proposed procedure, the tractions and displacements along the outer boundary are calculated. In the second step, the SIF for modes I, II, and III are derived in terms of simple boundary integrals over quantities known from the previous step. Contrary to Snyder's derivation, the determination of the SIF is based on the asymptotic displacement field at the crack tip. The method can easily be extended to multiple crack problems by using the subregion technique. (Edited author abstract). 17 Refs.

**080552 EXPERIMENTAL EVALUATION OF THE PLASTIC ZONES FOR STEADY MODE-III CRACK GROWTH.** A steady state quasi-static growth of a crack in antiplane shear in a strain hardening material was studied under small-scale yielding conditions. The extent of the plastic zone from the tip of the crack was determined as function of the size and geometry of the corresponding caustic developed around the crack tip. The method can be readily extended without considerable changes for large scale yielding. The topography of the plastically deformed zone was numerically and experimentally defined, its shape resembling a spiral ramp with its ground level coinciding with the crack axis and the two flanks of the ramp on either side of the crack axis going up or down until a complete half tour is covered. (Edited author abstract) 20 refs.

## Cracking

**080553 FINITE ELEMENTS FOR THE DETERMINATION OF PLASTIC ZONE AND MOUTH OPENING DISPLACEMENT (MOD) VALUES OF AN EDGE CRACKED THIN PLATE.** A finite element model is presented for the determination of plastic zone and Mouth Opening Displacement (MOD) values of an edge cracked thin mild steel plate. Singularity effects near the crack tip are solved by introducing 12 node cubic isoparametric elements in the crack tip region by collapsing into triangular elements. The initiation and expansion of the plastic zone is obtained by applying stepped nominal stresses of a tensile nature transverse to the crack length. The MOD values obtained by FEM are comparable with the values obtained experimentally. The stress intensity factors computed by this model are within 2-6% of the Westergaard solution. 25 refs.

**080554 STRESS INTENSITY FACTOR OF A SURFACE CRACK IN VISCOUS LUBRICATING OIL.** The squeeze effect of lubricating oil filling in a surface crack was calculated by using the finite element method.

An incremental procedure was presented to solve the two-dimensional Reynolds equation combined with the relation of the oil pressure to the crack opening displacement. As the crack is closing, the squeeze action increases the pressure of the lubricating oil, which tends to open the crack. For the constant crack depth,  $a = OD$  mm, the pressure produced by the squeeze action increases with a decrease in half-length of the crack,  $c$ . The contour lines of the pressure are roughly parallel to the surface of the plate, and so this pressure distribution is similar to those of a through crack in a thick plate. The distribution of the stress intensity factor due to the squeeze pressure is not significantly affected by the half-length of the crack,  $c$ . (Author abstract) 4 refs.

**080555 STRESS INTENSITY FACTOR FOR A DOUBLE EDGE CRACKED PLATE BY BOUNDARY COLLOCATION METHOD.** A set of complex functions for the double edge cracked plate is proposed. The boundary collocation method is used for estimating the stress intensity factors (SIF) and the results obtained by this method compare very favorably with existing solutions for many cases. Boundary collocation method has many advantages, such as simplicity, less computer time and sufficient accuracy for calculating SIF. (Edited author abstract). 13 Refs.

**080556 SINGULAR FUNCTIONS SUITED TO ANALYZE A FINITE VALUE OF STRESS CONCENTRATION NEAR THE END OF A CRACK TRAVERSING A PLATE.** Two singular stress functions suited to analyze crack problems of plates are presented. One of them is a stress function of two-dimensional problems which creates a crack opening displacement due to normal loads applied along the crack (mode 1) in an infinite plate. The other is the same function as that but due to shear loads along the crack (mode 2). The authors define these two functions as elementary crack function with opening of unit length. Superposing these functions with different length of elementary crack opening, the stress concentrations due to many cracks contained in the infinite plate can be analyzed numerically with good accuracy. The characteristic of this method is that the stress softening zones at both ends of the crack can be constructed where either crack opening displacements or stress concentrations with finite magnitude appear. (Author abstract). 19 Refs. In Japanese.

## Creep

**080557 DESCRIPTION OF CREEP HARDENING BY MEANS OF INTERNAL TENSOR VARIABLE.** To describe the first and second stages of creep in the case of the complex stressed state, we employ an internal variable of a tensor nature, namely the density tensor of the dislocation moment. The kinetic equations for the creep rate and rate of change of the internal variable make it possible to describe the anisotropic nature of creep hardening: the departure from proportionality of the deviators of the stress tensors and the creep rates as the form of the stressed state changes. It turns out that the exact meaning of the internal variable is not required for adequate description of the process of creep and change in internal energy in the case of structural changes. It is sufficient merely that this internal variable qualitatively reflect all processes that take place on the microlevel during the creep times. (Edited author abstract) 27 refs.

**080559 WAVES PRODUCED BY THE ELASTIC IMPACT OF SPHERES ON THICK PLATES.** An experimental and theoretical investigation of the elastic normal impact of spheres on thick plates has been carried out. The coefficient of restitution has been measured very carefully by observing the flight times of successive bounces of balls on glass plates and the displacements at the bottom face have been accurately measured with a laser heterodyne optical interferometer. The analysis along the axis of impact has shown two unexpected phenomena, namely the propagation of a longitudinal displacement at the shear wave velocity and an enhancement of the amplitude of the reflected 'P' wave at the free surface of the plate. Both of these have been confirmed experimentally. (Author abstract) 20 refs.

**080560 ANALYTICAL SOLUTION OF A REFINED SHEAR DEFORMATION THEORY FOR RECTANGULAR COMPOSITE PLATES.** The Levy type solution procedure in conjunction with the state-space concept is used to determine the deflections and stresses for symmetric laminated composite plates with rectangular geometries by using a refined shear deformation theory. Combinations of simply supported, clamped and free boundary conditions are considered. Numerical results are presented for rectangular plates with different edge conditions, aspect ratios, lamination schemes and loadings. The solution should serve as a reference for designers and practitioners of numerical/computational methods. (Author abstract) 16 refs.

Kheir, A.A. (Virginia Polytechnic Inst & State Univ, Blacksburg, VA, USA); Reddy, J.N.; Librescu, L. *Int J Solids Struct* v 23 n 10 1987 p 1447-1463.

**080561 EFFICIENT COMPUTER PROGRAM FOR THE LARGE DEFLECTION ANALYSIS OF RECTANGULAR ORTHOTROPIC PLATES.** A computer program is presented for the static analysis of rectangular specially orthotropic plates undergoing large deflections. In-plane loads and lateral pressure are both catered for, together with various combinations of boundary conditions. However, a restriction is that there must be symmetry about both plate axes. The plate can have an initial geometrical imperfection, which is represented by a double Fourier series with the same terms as that used for the lateral displacement. By specifying in the input data suitable values for the coefficients in the imperfection series, the effect of relatively complicated initial shapes can be examined. The program is called ELDAROP, a FORTRAN listing of which is given. Also given is a listing of the associated subroutine STRRES, which calculates stress resultants. (Edited author abstract) 11 refs.

**080564 SOLUTION AND THEIR COMPARISONS OF THE SANDWICH PLATE ANALOGY METHOD IN TWO KINDS OF SIMPLY SUPPORTED TWO-WAY ORTHOGONAL-DIAGONAL LATTICE GRIDS.** In this paper the sandwich plate analogy method is used to analyze the two-way orthogonal-diagonal lattice grids and then the basic sixth-order differential equations of this kind of space grid are given. For the rectangular plane grids with the first and second kinds of simply supported boundary conditions, their basic differential equations are analytically solved. In solving these equations, the solutions of the space grids under the first kind, that is, taking the solution of the double trigonometric series of the first kind of space grids as the special solution, and summing up the solution of the two single trigonometric series intersecting each other as the homogeneous solution, and then by using the boundary collocation method, the general solution is obtained. The authors compare the internal forces and the deflections of the space grids under the two kinds of simply supported conditions and point out that they are different, especially at the places near the boundaries and corners. **080565 STRESS ANALYSIS OF ANNULAR SANDWICH PLATES OF LINEARLY VARYING THICKNESS.** A small deflection theory is presented for stresses and deformations in variable thickness elastic annular sandwich plates that are symmetric about a middle surface. Both the energy expression and the differential equations are developed. In this analysis, the face sheets are treated as membranes, the core is assumed to be inextensible in the thickness direction, to carry only transverse shear stress on its cross sections normal to middle surface, and to be deformable in transverse shear. The theory takes into account the contribution of the face sheet membrane forces (by virtue of their slopes) to the transverse shear. (Author abstract) 6 refs.

**080567 RESPONSE OF A DAMPED QUADRILATERAL CANTILEVER PLATE.** The steady state response of an internally damped quadrilateral cantilever plate to a sinusoidally varying point force is determined by means of the Ritz method. An arbitrary quadrilateral plate is conveniently transformed into a unit square plate by a transformation of variables. The transverse deflection of the transformed square plate can be approximately expressed in a series of beam eigenfunctions, and the driving point impedance can be derived analytically. The present method is applied to the response calculation of a skew cantilever plate driven at an arbitrary point, and natural frequencies and corresponding mode shapes are also calculated. The effects of the aspect ratio, skew angle, damping factor and location of the driving point on vibrations of a skew cantilever plate are determined quantitatively. (Author abstract) 8 refs.

Ichinomiya, O. (Hokkaido Inst of Technology, Sapporo, Jpn); Maruyama, K.; Irie, T.; Yamada, G. *J Sound Vib v 122 n 1* Apr 8 1988 p 97-106.

**080568 STEADY STATE RESPONSE OF A CANTILEVER QUADRILATERAL PLATE DRIVEN BY A TRANSVERSE DEFLECTION.** Steady state response to a sinusoidally varying transverse deflection is determined for an internally damped cantilever quadrilateral plate by means of Ritz method. A quadrilateral plate of general shape is transformed into a square plate with unit length by a transformation of variables. The transverse displacement of the transformed square plate is approximately expressed in a series of the beam eigenfunction. Substituting the expressions for the kinetic energy and strain energy of the plate into Lagrange's equation, the equation of motion is developed. The dynamic response of the plate is determined by solving the equation of motion of the plate. Numerical work is done for the skew cantilever plate driven by a sinusoidally varying transverse deflection, and the steady state response of the plate is studied. (Author abstract) In Japanese. 10 refs.

**080569 DYNAMIC STABILITY OF AN INITIALLY DEFLECTED RECTANGULAR PLATE UNDER AN INPLANE DYNAMIC MOMENT.** Vibration of an initially deflected rectangular plate under a sinusoidally time-varying inplane moment is examined from the point of view of dynamic instability. The equation of motion describing the large deflection of the initially deflected plate is analyzed by the Galerkin method. The resulting equations for time variables are integrated by using the Runge-Kutta-Gill method. The dynamic instability regions are analyzed by the small deflection theory of a thin plate, neglecting nonlinear terms. The amplitudes of unstable regions are determined by large deflection theory. Numerical results are presented in various shapes and magnitudes of the initial deflection. The effect of the initial deflection on natural frequency, dynamic instability and amplitudes is discussed. (Edited author abstract) 7 refs.

**080570 STATISTICAL STUDY ON ULTIMATE STRENGTH CURVES OF LONGITUDINALLY STIFFENED PLATES UNDER UNIAXIAL COMPRESSION.** By processing statistically the data of initial deflection obtained from measurement of stiffened plate members in steel box girder bridges recently fabricated in Japan, its statistical properties can be made clear. On the basis of the initial deflection data, the ultimate strength curve corresponding to the probability of nonexceedance of 5% can be provided. Finally, the conception of

determining the allowable values as well as the procedure of test measurement for the initial deflection of stiffened plates are presented. (Author abstract) In Japanese. 32 refs.

**080572 BENDING OF SANDWICH PLATES OF VARIABLE THICKNESS.** A small deflection theory, consisting of differential equations and a total potential energy expression, is presented for determining the stresses and deformations in variable thickness elastic sandwich plates symmetric about a middle surface. The theory takes into account the contribution of the face-sheet membrane forces (by virtue of their slopes) to the transverse shear. A finite-difference formulation of the stationary total potential energy principle is presented along with an illustrative application. (Author abstract). 6 Refs.

**080573 EXACT SOLUTION OF NONLINEAR CIRCULAR PLATE ON ELASTIC FOUNDATION.** A large deflection problem of a concentrated loaded circular plate on an elastic foundation is treated. By means of a step-by-step iterative method, first the exact solution's analytic forms and their convergence are obtained. Then a numerical procedure, which can be carried out by computer, is given to calculate the exact solution of the problem with an arbitrary boundary condition. Last, the numerical results of the exact solution of the problem with a rigidly clamped boundary condition and  $\nu=0.3$  are obtained in detail. The results of the exact solution are more reliable than those of other approximate solutions. (Edited author abstract). 8 Refs.

**080574 LARGE DEFLECTIONS OF SIMPLY SUPPORTED ISOSCELES TRIANGULAR PLATES SUBJECTED TO EDGE SHEAR AND COMPRESSIVE LOADING.** The large deflection analysis of simply supported isotropic isosceles triangular plates using the principle of minimum energy is presented for two types of loading conditions. The analysis is restricted to plates whose edges are constrained to remain straight after buckling. The results of the analysis are used to estimate the ultimate loads for the plate subjected to loading under this constraint. An estimate of the ultimate loads for unconstrained isosceles triangular plates is obtained using Von Karman's effective width hypothesis. (Author abstract). 8 Refs.

**080575 BENDING OF A UNIFORMLY LOADED ANNULAR PLATE WITH MIXED BOUNDARY CONDITIONS.** This paper deals with the analytical solution of a uniformly loaded annular plate in which the inner edge is free and the outer edge restricted by a system of simple and fixed supports. The boundary conditions of the annular plate are thus mixed between the simple and fixed supports. The solution is set up by using the deflection equation, and the mixed boundary conditions are written in the form of dual-series equations. By

choosing the proper finite integral transform, the dual-series equations can be written in the form of an inhomogeneous Fredholm integral equation. This equation, with a numerical technique, is then reduced to a set of simultaneous equations suitable for numerical solution. The deflections, bending moments, and moment concentration of the annular plate are calculated. (Author abstract). 11 Refs.

**080576 LARGE DEFLECTION OF CIRCULAR PLATES WITH OR WITHOUT HOLE AT CENTER.** The objective of this study is to assess the accuracy and computational efficiency of the equivalent load concept in the analysis of circular and annular plates undergoing large deflection in the sense of von Karman theory. Solutions for von Karman-type circular and annular plates were obtained by considering equivalent plates with small displacements, where the nonlinear terms of lateral displacement were treated as fictitious loads acting on the plate. In this way, solutions for many difficult nonlinear elastic plate problems may be obtained by using the known solutions of the linear problems through an iteration procedure. Results for uniformly loaded circular and annular plates have been shown to be in good agreement with the available solutions. 6 Refs.

**080577 LARGE DEFLECTION AXISYMMETRIC ANALYSIS OF ORTHOTROPIC ANNULAR PLATES ON ELASTIC FOUNDATIONS.** Large deflection axisymmetric response of cylindrically orthotropic thin annular plates, resting on annular elastic foundations and subjected to uniformly distributed loads are presented. Static and step function loads applied to clamped and simply supported annular plates are considered. The natural boundary conditions employed at the hole are consistent with those obtained from Hamilton's principle. Von Karman type governing equations are solved using the orthogonal point collocation method in conjunction with the Newmark- $\beta$  scheme. The maximum response to step loads obtained from static analysis is shown to agree very well with that obtained from a transient analysis. Thus one static analysis is sufficient to obtain the maximum response to a whole set of step loads. (Edited author abstract). 11 Refs.

**080578 INCREMENTAL GALERKIN METHOD FOR PLATES AND STIFFENED PLATES.** In order to perform a detailed analysis of large deflection behavior of a rectangular plate or stiffened plate, an efficient semi-analytical method is developed. First, incremental forms of the governing differential equations of plates and stiffened plates with initial deflection are derived. These equations are linearized and may be easily solved. Secondly, these equations are solved for each load increment by the Galerkin method with a special consideration of simply supported boundaries. A procedure of equilibrium correction at intermediate load steps is presented such that good accuracy of the solution may be maintained with larger load steps. This method is successfully applied to plates with initial deflection subjected to in-plane as well as out-of-plane loads to obtain the whole histories of the behavior of these plates. **080579 EFFECT OF PULSE SHAPE AND DISTRIBUTION ON THE PLASTIC DEFORMATION OF A CIRCULAR PLATE.** The dynamic plastic deformation of a simply-supported circular plate subjected to a pressure distribution, which is an arbitrary function of radius and time, is found to depend on the moment history applied by the pressure and the moment history applied by the pressure excess over a conical distribution. Each of these moment histories can be replaced by an equivalent rectangular pulse in determining the final deformation at the center of the plate. (Author abstract) 22 Refs.

**080580 ON HIGHER ORDER SHEAR DEFORMATION THEORY OF LAMINATED COMPOSITE PANELS.** In this paper we examine the suitability of higher order shear deformation theory based on cubic inplane displacements and parabolic normal displacements, for stress analysis of laminated composite plates including the interlaminar stresses. An exact solution of a symmetrical four layered infinite strip under static loading has been worked out and the results obtained by the present theory are compared with the exact solution. The present theory provides very good estimates of the deflections, and the inplane stresses and strains. Nevertheless, direct estimates of strains and stresses do not display the required interlaminar stress continuity and strain discontinuity across the interlaminar surface. On the other hand, 'statically equivalent stresses and strains' do display the required interlaminar stress continuity and strain discontinuity and agree very closely with the exact solution. (Author abstract) 16 Refs.

**080581 R-FUNCTION METHOD IN PROBLEMS OF NONLINEAR DEFORMATION OF PLATES.** The problem of solving geometrically nonlinear problems of the theory of plates is treated in a vast literature. However, numerical results are obtained basically for plates having canonical form, e.g., disk, square. In this paper we deal with the solution of problems of bending of elastic plates and use an approach based on a simultaneous applications of the theory of R-functions, variational Ritz principle, and the method of consecutive approximations. This permits one to perform the calculation of plates of practically arbitrary form. 5 Refs.

**080582 ACCURATE, SIMPLIFIED METHOD FOR ANALYZING THIN PLATES UNDERGOING LARGE DEFLECTIONS.** The present analysis examines the behavior of thin, circular, isotropic plates considering geometric nonlinear behavior but not material nonlinearity. The circular plates examined were solid with a fully clamped outer boundary. An approximate solution was determined with the aid of MACSYMA, a symbolic manipulation computer program, using the energy method. The loading cases examined were: a uniform pressure load and a central point load. The solution was based upon a two-term trial function for the plate deflection, with the coefficients written in a new way. This type of trial function allows the dimensionless deflection profile to vary with the loading. This is an improvement over many existing solutions. Results are given for dimensionless plate center deflection and dimensionless radial bending stress at the plate center. (Edited author abstract) 19 Refs.

**080585 STABILITY OF PURE HOMOGENEOUS DEFORMATIONS OF AN ELASTIC PLATE WITH FIXED EDGES.** An analysis is given of the stability of pure homogeneous deformations of an incompressible elastic plate. The two faces of the plate are free and the displacement of its edge is prescribed. Pointwise conditions for stability are derived by using Fourier transforms and constructing a special displacement field. The conditions obtained are related to a restricted rank-two convexity condition of the strain energy function. Such a condition is then studied for isotropic materials, resulting in a set of inequalities in terms of the strain energy function and principal stretches. (Author abstract). 12 Refs.

**Design** See Also STRUCTURAL DESIGN—Optimization.

**080586 OPTIMAL DESIGN OF PLATES RESTING ON TENSIONLESS FOUNDATION.** The problem of optimal design of thin solid plates resting on a Winkler-type tensionless elastic foundation under static loading is discussed. Having divided the plate domain into finite elements, we use the plate thickness of each element as the design variable. The volume of the plate is taken as the objective function. Some constraints related to the allowable stresses in the plate and the foundation, besides both the maximum and minimum allowable thickness of the plate, are imposed. The optimality criterion derived for the problem dealing with the displacement constraint enables us to develop an effective numerical procedure based on successive iterations. In the last stage of the procedure it is possible to eliminate elements with a thickness decreasing below a minimum point, and consequently the optimal shape of the plate domain may be formed. Some numerical examples of the optimal design of steel plates are given. (Edited author abstract) 6 Refs.

## Elasticity

**080588 DEFINITION OF ELASTIC MODULI FOR PLATES MADE FROM THICKNESS-UNEVEN ANISOTROPIC MATERIAL.** A plate is interpreted as a Cosser's two-dimensional continuum. A possible construction of a set of equations describing such a continuum has been presented in a paper by P.A. Zhilin. The present paper examines only the linearized particular case from it. The definition of elastic moduli of a plate made of a thickness-inhomogeneous anisotropic material is investigated in detail. The modulus formulas derived in the paper are most general from among the expressions offered in the literature on the theory of multilayer and inhomogeneous plates. (Edited author abstract) 8 refs.

Altenbach, H. *Mech Solids* v 22 n 1 1987 p 135-141.

**080589 DEVELOPMENT OF THE BIFURCATION CONDITION FOR A THICK ELASTIC PLATE.** A consistent six-term asymptotic series is derived for the critical value of the deformation parameter as a function of aspect ratio (thickness: height), in the limit as this ratio becomes unbounded, for a plate of general incompressible isotropic material. Values for both flexural and barreling modes are obtained in the case where the loading is a thrust. The theoretically important class of Mooney-Rivlin materials is treated as a special case. (Author abstract) 11 refs.

**080590 TRANSIENT IMPACT RESPONSE OF THICK CIRCULAR PLATES.** The finite element method was used to study the transient response of thick circular plates subjected to point impact. The response of plates having different geometries and subjected to impacts of different duration was studied in both the time and the frequency domains. It is shown that the transient plate response is composed of a number of different modes of vibration including P- and S-wave thickness modes, antisymmetric flexural modes, the rod mode, and P- and S-wave diameter modes. The origin of the diameter modes is discussed. Excellent agreement was found between the calculated frequency values and those obtained from finite element analyses. (Author abstract) 16 refs.

**080592 PLATES ON BIPARAMETRIC ELASTIC FOUNDATION BY BDIE METHOD.** An efficient boundary differential integral equation (BDIE) method is presented for the analysis of thin elastic plates with free boundaries of any shape resting on biparametric elastic foundation. The plate, which may have holes, is subjected to concentrated loads, line loads, or distributed surface loads. The solution is achieved by converting the governing boundary value problem to an equivalent problem consisting of five coupled boundary equations, two of which are differential and three of which are integral. The boundary differential equations are derived from the boundary conditions, while the boundary integral equa-

tions are derived from the integral representations for the deflections of the plate and of the foundation region. A numerical technique based on the discretization of the boundary is developed for the solution of the boundary equations. The computational efficiency of the method is increased by converting the domain integrals attributable to loading into boundary line integrals. (Edited author abstract) 19 refs.

**080593 ELASTIC ANALYSIS OF PARTIAL CONTACT PROBLEMS IN A UNIAXIALLY LOADED PLATE WITH AN INTERFERENCE-FIT ELLIPTIC PLUG.** This paper is concerned with the mixed boundary-value problems of an infinite plate with an elliptic hole, into which a smooth rigid elliptic plug is simply inserted. Since the infinite plate is subjected to a uniaxial loading (tension or compression) at infinity, apertures are produced along the boundary between the inserted plug and the hole. The contact pressure between the inserted plug and the hole is expressed in a convergent series whose differential form is also convergent, so that the stress and displacement generated along the boundary can be numerically analyzed by the point-matching method. Using the numerical results for various elliptic shapes, the influence of interferences is shown with the stress around an elliptic hole. (Author abstract) 5 refs.

**080595 THREE-DIMENSIONAL ELASTIC-PLASTIC J-INTEGRAL CALCULATIONS FOR SEMIELLIPTICAL SURFACE CRACKS IN A TENSILE PLATE.** Using a finite element method, in conjunction with an equivalent domain integral approach, the elastic-plastic crack-tip J-integral is computed for semielliptical surface flaws in a plate under a remote tensile load. The computed elastic-plastic values of the J-integral are compared to the elastic ones. It is concluded that a linear elastic fracture mechanics approach can be used for semielliptical cracks of relative depth of  $a/t = 0.25$  and aspect ratio of  $c/a \leq 3$ , up to load levels of  $0.9\sigma_y$  with an error of no more than 10% in the (equivalent) elastic-plastic stress intensity factor. A simple empirical equation for evaluating the elastic-plastic J-integral for surface flaws is proposed. (Author abstract) 9 refs.

**080596 ELASTIC PLASTIC ANALYSIS OF AN ELLIPTICAL HOLE IN AN INFINITE PLATE UNDER VARIOUS COMBINED REMOTE STRESS BY THE COMBINATION OF FINITE ELEMENT METHOD AND BODY FORCE METHOD.** A method of elastic-plastic stress analysis based on the combination (FEM+BFM) of finite element method (FEM) and body force method (BFM) is developed. FEM+BFM has the advantages of both method (FEM and BFM) and has

many possible applications. The line elements of BFM are located along the interface between the outer elastic domain and the inner elastic-plastic domains which are composed with FEM elements. In the present study, the method is applied to solve the problems of an elliptical hole contained in an infinite plate under various combined remote stress ( $\sigma_{x\infty}$ ,  $\sigma_{y\infty}$ ,  $\tau_{xy\infty}$ ). The stress and strain concentration, the extension of plastic zone and the applicability of Neuber's rule under various combined remote stress ( $\sigma_{x\infty}$ ,  $\sigma_{y\infty}$ ,  $\tau_{xy\infty}$ ) are investigated in details. (Author abstract) In Japanese. 8 refs.

**080597 ELASTIC-PLASTIC SNAPPING-THROUGH OF A CURVED METAL STRIP COMPRESSED BETWEEN TWO RIGID PLATES.** The quasi-static loading of a curved strip compressed by a flat, rigid plate is considered, with particular references to large deformations and the ensuing buckling behavior. Experiments were performed on curved strips of constant width, but of different thickness. The strips were initially deformed to a fixed radius of curvature and stress was relieved before pinning the ends. The deformation characteristics have been analyzed using an incremental finite element technique. Particular attention has been paid to modeling the situation when a node contacts the plate and the condition for separation of the strip from the plate. The predicted loads and deformation modes agreed well with experimental results from tests on steel and aluminum specimens. The experimental and theoretical procedures are pertinent to the study of dent resistance of sheet metal stampings, particularly for automotive panels. (Author abstract) In Japanese. 17 refs.

**080598 RESEARCH ON THE TEST OF ELASTO-PLASTICITY AND FAILURE MECHANISM OF GUSSET PLATE ON PANEL POINTS OF STEEL TRUSS.** The results of 24 tested pieces of welded gusset plate in 10 different constructing forms on panel points of double-angle steel truss are introduced. The stress field on the plate is divided into tensile and compressive according to the relationship between its principal sectional stresses, and its failures are classified as yielding of the compressive region and tearing of the tensile region. Conclusion is that the yielding and tearing zones should be considered as the critical area in gusset plate design, the strain capacities of high stress area both in tearing zone of tensile region and in buckle yielding zone of compressive region should be limited and the ratio of width to thickness should be limited. (Edited author abstract) 5 refs. In Chinese.

**080599 RESULTS AND EXPERIMENTS OF THE FINITE ELEMENT ANALYSIS OF ELASTO-PLASTIC PLATES.** The aim of this research was to determine the factors affecting the results and to follow the behavior of the elasto-plastic thin plates under static and dynamic loading. The solution of plate problems via the classical route is limited to relatively simple plate geometry, load and boundary conditions. If these conditions are more complex numerical and approximate methods are the only approaches that can be employed. In the engineering application it is important to be aware of the magnitude of the error of solution and of its components such as error of input data, error of calculation, economy of solution, machine error, human error etc.

**080600 PROCEDURE FOR REGULARIZATION OF SINGULAR INTEGRAL EQUATION OF THE MULTIPLE CRACK PROBLEM IN AN INFINITE**

**PLATE.** The regularization of the singular integral equation arising from the crack problems in plane elasticity is an important problem in fracture analysis. Several works have been done in the field of regularizing the singular integral equation. An alternate procedure of regularizing the singular equation in the crack problem has been carried out. In this paper it is pointed out that the system of singular integral equations arising from the multiple crack problem in an infinite plate can be also converted into a system of Fredholm integral equations by the use of the second procedure. 9 refs.

**080605 FRACTURE CRITERION OF NOTCHED PLATES OF FRP.** The influence of notches on static tensile strength was studied for a composite material. Tension tests of notched plate for glass cloth/epoxy

laminates have been carried out for a wide range of notch tip radii. All notched specimens failed in a brittle manner through the formation of small deformation near the notch tip. The experiment shows that the nominal stress at failure decreases with decreasing notch tip radius and it approaches a constant value when the notch tip radius is less than about 0.2 mm. It has been verified that the maximum elastic stress at the notch tip when the specimen fails is governed by notch tip radius alone, and is independent of notch depth. On the basis of the concept of linear notch mechanics, the experimental results mentioned above can be clearly explained, and the limiting condition for the fracture of notched plates of composite materials is expressed. (Edited author abstract) 15 refs. In Japanese.

**Fatigue** See Also METALS TESTING—Tensile Tests.

**080607 CONSTITUTIVE BEHAVIOR OF A MICROCRACKING BRITTLE SOLID IN CYCLIC COMPRESSION.** A constitutive formulation is presented to determine the 'driving force' for Mode I fatigue crack growth in notched plates of brittle solids stressed in uniaxial cyclic compression. For the particular case of a microcracking medium, it is demonstrated that residual tensile stresses are induced ahead of the notch during unloading from the maximum far-field compressive stress. We propose that it is the region of residual tensile stresses at the notch-tip which promotes fatigue crack growth in ceramics along the notch plane in a direction normal to the compression axis. The predictions of the analysis are compared with new experimental results on compression fatigue in brittle solids. Specifically, it is shown that the numerical estimates of the near-tip tensile zone size for microcracking ceramics compare favorably with the experimentally measured distance of stable Mode I fatigue crack growth after the first compression cycle. (Edited author abstract) 19 refs.

**080608 FATIGUE LIFE AND FATIGUE CRACK THROUGH-THICKNESS BEHAVIOR OF A SURFACE-CRACKED PLATE (EFFECT OF STRESS CONCENTRATION).** Most structures have a region where stresses concentrate, and the probability of fatigue crack initiation may be higher than in other parts. Therefore, to improve the reliability of an LBB (Leak Before Break) design, it is necessary to evaluate the growth and through thickness behavior of fatigue cracks in the stress concentration region. In this paper, the fatigue crack growth behavior in a stress concentration region has been studied on 3%NiCrMo and HT80 steels. Stress concentration was caused by a fillet on the plate. Before cracking through the plate thickness, stress concentration has a remarkable effect on the fatigue crack growth behavior and it flattens the shape of a surface crack. The crack growth behavior can be explained quantitatively by using the Newman-Raju formula and the stress resolving method proposed by ASME B&P Code Sec.XI. (Edited author abstract) 14 refs.

**080609 QUANTITATIVE PREDICTION OF GROWTH PATTERNS OF SURFACE FATIGUE CRACKS IN TENSION PLATES.** Different methods of prediction of the aspect ratio variability of growing surface fatigue cracks in tension plates are compared with experimental data. The objective is to identify the most accurate method. The comparison is based on a quantitative criterion as well as on statistical examination of the level of agreement with the data. Fifty-eight cracks are analyzed. The total number of data points is 450 taken from 20 references. The solutions evaluated include theoretical as well as empirical formulas. The comparison shows that it is possible to predict the aspect ratio variability with standard deviation  $<0.070$ . (Author abstract) 29 refs.

**080611 INFLUENCE OF AN ABRUPT CHANGE IN THE THERMAL BOUNDARY CONDITIONS ON THE TURBULENT BOUNDARY LAYER ON A PLATE.** The development of the thermal boundary layer within a dynamic layer that has already been formed is a situation encountered in the practice of analyzing heat exchangers. The formulation of this problem is represented schematically. A homogeneous thermal flux acts on a plate. The Patankar-Spalding finite-difference method of solving the system of boundary layer differential equations is used in this paper to solve the formulated problem. The method underestimates the value of the Stanton number  $St$ , especially near the section  $x = x_0$ , where the discrepancy between the experimental results computation exists. 7 refs.

**080613 RIGID-PLASTIC RESPONSE OF FLOATING PLATES.** This paper presents the exact formulation and solution for the static flexural response of a rigid perfectly plastic freely floating plate subjected to lateral axisymmetric loading. The Tresca yield condition is adopted with the associated flow rule. The plate response is divided into three phases: Initially the plate moves downward into the foundation as a rigid body (Phase I). Subsequently the plate deforms in a conical mode in addition to the rigid body motion (Phase II). At a certain value of the load a hinge-circle forms which may move as the pressure increases further (Phase III). The nature of

the solution during the third phase depends upon the parameter  $\alpha=a/R$  (ratio of radius of loaded area to the plate radius). (Edited author abstract). 9 Refs.

## Foundations

**080615 UNBONDED CONTACT OF A SQUARE PLATE ON AN ELASTIC HALF-SPACE OR A WINKLER FOUNDATION.** The unbonded frictionless receding contact problem of a thin plate placed under centrally symmetric vertical loading while resting on an elastic half-space or a Winkler foundation is solved in this paper. The problem is transformed into the solution of two-coupled integral-series equations over an unknown contact region. The problem is nonlinear by virtue of unilateral contact and therefore needs to be solved iteratively. Special attention is given to the edge and corner contact pressure singularities for the plate on the elastic half-space. Comparison is made with other relevant numerical results available. (Author abstract). 29 Refs.

## Fracture See Also ROLLING MILL PRACTICE.

**080616 MIXED-MODE CRACK GROWTH IN PLATES UNDER THREE-POINT BENDING.** A combined theoretical and experimental study of the problem of crack growth in a plate subjected to unsymmetrical three-point bending was undertaken. The opening-mode  $K_I$  and sliding-mode  $K_{II}$  stress-intensity factors describing the local stress field around the crack tip were determined by a finite-element computer program. The crack growth was analyzed by the maximum circumferential stress and the minimum strain-energy density criteria. The critical loads for crack growth and the crack trajectories were determined both by theory and experiment. The experimental results corroborated the theoretical predictions. (Author abstract) 10 refs.

**080617 ASYMPTOTIC METHOD OF HOMOGENIZATION OF FISSURED ELASTIC PLATES.** This paper deals with the homogenization of thin elastic plates weakened by periodically distributed fissures. The classical Kirchhoff theory of bending plates admits five different types of unilateral fissures. To derive effective properties of fissured plates we employ the asymptotic method. As a result we obtain five effective hyperelastic plates. An illustrative example concerns the homogenization of the plate with unidirectional fissures parallel to a straight line. The constitutive equation describing the effective plate is found provided that fissures are of the flexural type resembling that observed in reinforced concrete plates in bending. **080619 STATISTICAL ANALYSIS OF FRACTURE ARREST TOUGHNESS OF VARIOUS STRUCTURAL STEEL PLATES.** A statistical investigation was made relating to the brittle fracture arrest properties of various steel plates for ship and bridge structures, low-temperature storage tanks and pressure vessels. Fracture arrest toughness ( $K_{Ia}$ ) data obtained by means of the temperature gradient type of ESSO tests on around 200 steel plates were collected and analyzed. It was found that  $K_{Ia}$  transition curves in terms of temperature for a set of steel plates possessed a 'pivot' on the temperature versus  $K_{Ia}$  diagram when the data were grouped according to their chemical composition and production methods. It was also found that the new production method of Thermomechanically Controlled Process (TMCP) for plate rolling provides an effective measure to improve the fracture arrest properties of steel plates. ## Glass

**080620 STRENGTH OF WINDOW GLASS PLATES SUBJECTED TO RAPID LOADING.** The strength of a glass plate is known to be time dependent; that is, the plate has a greater capacity to withstand pressures of brief duration than sustained pressures. This phenomenon is a very important consideration in designing window glass plates for short duration loads resulting from strong winds or blast pressures. The purpose of this research is to provide experimental data that will allow for the following: verification of the commonly accepted value of the static fatigue coefficient,  $n$ , at loading rates beyond 3.6 psi/sec; experimental verification of finite difference analytical predictions of dynamic plate response; and verification of the Norville dynamic failure prediction model. The data obtained from this experimental study will provide a bridge between present knowledge of the behavior of glass plates under static loading and that under rapid loading. 10 refs.

**080622 FREE CONVECTION FROM A VERTICAL PLATE WITH CONCENTRATED AND DISTRIBUTED THERMAL SOURCES.** An analysis is developed for the laminar free convection from a vertical plate with uniformly distributed wall heat flux and a concentrated line thermal source embedded at the leading edge. We introduce a parameter to describe the relative strength of the two thermal sources; and propose a unified buoyancy parameter to properly scale the dependent and independent variables. The variables are so defined that the resulting nonsimilar boundary-layer equations can describe exactly the buoyancy-induced flow from the dual sources with any relative strength to fluids of any Prandtl number from very small values to infinity. The effects of both relative source strength and Prandtl number on the velocity profiles, temperature profiles, and the variations of wall temperature, are clearly illustrated. **080631 ELASTIC ANALYSIS OF PIN JOINTS IN PLATES UNDER SOME COMBINED PIN AND PLATE LOADS.** A circular pin in a circular hole in an infinitely large plate is considered. A two-dimensional plane-stress analysis of such a configuration is carried out, here, subjected to pin-bearing and/or biaxial-plate loading. The pin is assumed to be rigid compared to the plate material. The pin-hole interface is unbonded and so beyond some load levels the plate separates from the pin and the extent of separation is a non-linear function of load level. The problem is solved by inverse technique. In the situations where combined load is acting the separation-contact zone specification generally needs two parameters (angles) to be specified. The present report deals with analyzing such a situation in metallic (or isotropic) plates. Numerical results are provided for parametric representation and the methodology is demonstrated. 9 refs.

**080636 ANALYSIS OF CIRCULAR PLATE-ELASTIC HALF-SPACE INTERACTION USING AN ENERGY APPROACH.** An analytical formulation is developed, based on an energy approach, to predict the flexural behavior of uniformly loaded thin flexible circular plates resting in smooth and continuous contact with an isotropic elastic half-space. In this development, the deflected shape of the plate is approximated by an even power series expansion in terms of the radial coordinate. Any number of terms in the series can be considered. The coefficients associated with the series are evaluated by making use of the principle of minimum potential energy. Analytical expressions are derived for the contact stress distribution, the plate deflection, and the plate radial moment. The results obtained from the proposed procedure compare very well with the existing solutions of similar problems. (Author abstract) 15 refs.

**080638 FREE-FORM PLATE MODELING USING OFFSET SURFACES.** This paper addresses the representation of plates within the framework of the Boundary Representation method in a Solid Modeling environment. Plates are defined as the volume bounded by a progenitor surface, its offset surface and other, possibly ruled surfaces for the sides. Offset surfaces of polynomial parametric surfaces cannot be represented exactly within the same class of functions describing the progenitor surface. Therefore, if the offset surface is to be represented in the same form as the progenitor surface, approximation is required. A method of approximation relevant to non-uniform rational parametric B-spline surfaces is described. (Edited author abstract). 14 Refs.

**Mechanical Properties**

**080639 STIFFNESS TAILORING FOR IMPROVED COMPRESSIVE STRENGTH OF COMPOSITE PLATES WITH HOLES.** A structural optimization procedure is used to obtain minimum-mass designs of compression-loaded composite plates with holes by tailoring the plate cross-sectional stiffnesses. The plate cross sections consist of two different balanced symmetric laminates with 0,  $\pm 45$ , and 90 deg piles. The plate inner laminate contains a hole and is designed from a softer material system with a higher failure strain than the plate outer laminate. All-graphite-epoxy plates and hybrid graphite/glass-epoxy plates were studied. Results for designs with different percentages of 0 and  $\pm 45$  deg piles in the outer laminate are compared with results for the optimum designs. Results for design with uniform cross-sectional stiffnesses are also compared with the results for tailored cross-sectional stiffness designs. Specimens of each design were tested to verify the analytical predictions. The results show that cross-sectional stiffness tailoring can increase the ratio of compressive strength to mass of compression-loaded laminated plates with holes.

## Physical Properties

**080645 RESEARCH ON CALCULATION OF STRUCTURALLY ORTHOTROPIC PLATE RIGIDITY.** A composite structure of rib-plate is always calculated as a structurally orthotropic plate. The calculating precision of such an analogy mostly depends on whether the determination of rigidity is proper or not. In this paper, the physical concept of each item in rigidity is analysed first, and the torsional rigidity and the items in rigidity used for calculating internal forces are then derived. It clears up the confusion caused by the misunderstanding of the physical meanings of rigidity. A virtual plate method for the plate strengthened by equidistant stiffeners in longitudinal direction is also recommended in this paper. It has been proved by experiments that this method is effective for improvement of calculating precision. Its extension and application may provide another way for the approximate calculation of composite structures and the numerical analysis methods. (Edited author abstract) 10 refs. In Chinese.

## Plasticity

**080646 APPROXIMATE EVALUATION OF PLASTIC ZONES IN PLATES WITH OPENINGS.** A load applied to a plate with an opening produces in certain conditions a local stress concentration near selected points on the opening edges. Near such points, known as stress concentrators, plasticity regions may develop. For a theoretical definition of plastic strains, a highly complex elastoplastic problem has to be studied. The difficulty is compounded by the fact that the shape of the plasticity region is not known in advance. An approximate distribution of plastic zones at the corners of a curvilinear square opening in a plate subjected to symmetric uniaxial extensions is formulated with respect to the plate's thickness. **080647 PLASTIC WRINKLING OF AN ANNULAR PLATE UNDER UNIFORM TENSION ON ITS INNER EDGE.** This paper analyses the plastic wrinkling of an annular plate subjected to in-plane uniform tension stress on its inner edge with the combined use of the Kantorovich method and the Galerkin method, and discusses the appearance of wrinkles on the flange of a metal circular sheet during its axisymmetric deep-drawing operation. It is shown that the method provided in this paper is simple, convenient, and very suitable for engineering applications. (Author abstract) 9 refs.

**080648 DUALITY THEOREM FOR PLASTIC PLATES.** The duality theorem for a class of plastic plates is established in this paper. The family of  $\beta$ -norms is used to represent the yield functions. Exact solutions for circular plates under a uniform load are obtained for clamped and simply supported boundaries as examples of the specific duality relations. Two classical solutions

associated with H. Tresca and K.W. Johansen yield functions are also presented in the spirit of their own duality relations, providing interesting comparison to the new solutions. A class of approximate solutions by a finite element method is also presented. (Edited author abstract) 23 refs.

## Pressure Effects

**080649 CIRCLE-POLYGON PARADOX IN THE LIGHT OF THE BOUNDARY-ELEMENT METHOD.** The boundary-element method (BEM) is used to study the so-called circle-polygon paradox of simply supported thin plates under uniform pressure. A collocation approach is used to show that the correct assumption of boundary conditions for this problem eliminates the paradox. The computational efficiency of the method is discussed and its simplicity emphasized. (Author abstract) 5 refs.

## Protective Coatings

**080650 TiB<sub>2</sub> COATINGS ON PHOSPHOR BRONZE PLATES BY CVD AND THEIR PROPERTIES.** A phosphor bronze plate was coated with a thin layer of TiB<sub>2</sub> from a gas mixture of TiCl<sub>4</sub>, BCl<sub>3</sub>, H<sub>2</sub> and argon at temperatures of 580-850°C. The oxidation and corrosion stabilities were examined. Uniform and adherent TiB<sub>2</sub> layers were obtained on the phosphor bronze plate in the temperature range of 600-700°C. The deposition rates were 1.1  $\mu\text{m h}^{-1}$  and 2.2  $\mu\text{m h}^{-1}$  at temperatures of 700°C and 750°C respectively. TiB<sub>2</sub>-coated phosphor bronze plates were stable to oxidation at temperatures below 600°C and were slightly affected by 3.2 N HNO<sub>3</sub> at room temperature and concentrated HCl at 60°C. ## Shock Waves

**080651 EFFECT OF LOCAL CONTACT BEHAVIOR ON AN IMPACT LOAD DUE TO COLLISION BETWEEN A PLATE AND A SPHERE.** In the collision between the flat surface of solid and of a sphere, it can be considered that a high stress will occur, since an impact load is applied in a small local contact area. It is important when formulating the impact load that the effect of the local plastic deformation of the contact surface on the time history of a load due to impact is investigated. On the other hand, it is revealed by Hertz's theory that the relationship between a force and the amount of approach of both solids during impact is nonlinear. In this paper, the effect of the local displacement behavior in the contact process on the impact load is shown by the experiment of a collision between a plate of mild steel and a high hardness steel ball. The impact load is evaluated by a piezoelectric plastic transducer. The limitation which the modified approach of Hertz's theory is valid, are distinguished. (Edited author abstract) In Japanese. 6 refs.

**080652 ELASTIC STABILITY ANALYSIS OF THIN PLATE BY THE BOUNDARY ELEMENT METHOD - A NEW FORMULATION.** A new bound-

any integral equation formulation for the elastic stability analysis of thin plate is presented in this paper. This formulation involves only two kinds of integral equations which are similar to those employed in the linear analysis of plate bending problems by the boundary element method and are suitable to plates with arbitrary plan forms and under general boundary conditions or in-plane load conditions. A new simple boundary element discretization scheme is established based on these integral equations. Satisfactory numerical results obtained on a microcomputer with constant elements clearly show the applicability and efficiency of the approach developed in this paper. (Author abstract) 29 refs.

**080654 CONSTRUCTION OF DYNAMIC INSTABILITY DOMAINS OF PLATES AND SHELLS.** The numerical construction of the dynamic instability domains (zones) of plates and shells under simple and combined parametric resonances caused by the action of longitudinal periodic loads are studied. Formulation of the problem assumes the unperturbed stress-strain state (SSS) to be a membrane state and determined from the solution of the linear problem. The change in the coupled-stress SSS is negligibly small when perturbations are superposed on the kinematic parameters of the system characterizing the bending. This corresponds to the traditional formulation of the problem of parametric plate and shell vibrations. 7 refs.

**080655 NUMERICAL-ANALYTIC STABILITY ANALYSIS OF STIFFENED RECTANGULAR PLATES.** We propose a method for calculating the critical buckling stresses of rectangular plates with an arbitrary number of stiffening elements and various edge conditions. The basic difficulties in analytic solution of the problem are associated with selecting the system of basis functions in terms of which the sought function is expanded into a series. A method is constructed using step-type basis functions, making it possible to combine the advantages of the analytic solution with the universality of the numerical approach. 2 refs.

**080657 DYNAMIC STABILITY OF A RECTANGULAR PLATE SUBJECTED TO DISTRIBUTED IN-PLANE DYNAMIC FORCE.** Dynamic instability of a rectangular plate subjected to an in-plane sinusoidally varying force which varies along the edges is analyzed. The

thin plate small deflection theory is used. The boundary conditions of the plate consist of combinations of simply supported edge and clamped edge. Unstable regions are presented for various boundary conditions of the plate and loading conditions. (Author abstract) 7 refs.

Takahashi, K. (Nagasaki Univ, Nagasaki, Jpn); Konishi, Y. *J Sound Vib* v 123 n 1 May 22 1988 p 115-127.

**080658 ELASTIC STABILITY OF PLATES WITH AND WITHOUT OPENINGS.** The finite element method of analysis is used to determine the elastic buckling loads for plates with and without openings. The formulation is based on Mindlin plate theory. The 8-node serendipity element was employed to model the membrane behaviour of the plate in order to determine the in-plane stress distribution throughout the plate due to the edge loading. The heterosis plate bending element was used in the formulation of the governing equations of the stability problem. The elastic buckling loads for plates with and without openings and under different edge loading conditions are determined and the results were compared with the analytical and numerical results available. The openings considered are circular and square located at the centre of the plate. Convergence of the solution for the plates considered is also discussed. (Author abstract) 10 refs.

**080659 STABILITY OF PURE HOMOGENEOUS DEFORMATIONS OF AN ELASTIC PLATE WITH FIXED EDGES.** An analysis is given of the stability of pure homogeneous deformations of an incompressible elastic plate. The two faces of the plate are free and the displacement of its edges is prescribed. Pointwise conditions for stability are derived by using Fourier transforms and constructing a special displacement field. The conditions obtained are found to be related to a restricted rank-two convexity condition of the strain-energy function. Such a condition is then studied for isotropic materials, resulting in a set of inequalities in terms of the strain-energy function and principal stretches. (Author abstract). 12 Refs.

**080661 PRODUCTION OF HEAVY-GAUGE STEEL PLATES SUITABLE FOR HIGH-HEAT INPUT WELDING IN THE ARCTIC REGION.** For application to the energy resources development in the Arctic region, the YP 36 kgf/mm<sup>2</sup> class structural steel plates (maximum 70 mm in thickness), which have high toughness for high heat input welding, have been developed and manufactured using the multipurpose accelerated cooling system (MACS). This steel contains a small amount of Nb for the purpose of reducing C and Mn contents. Its carbon equivalent is reduced by utilizing MACS and its mechanical properties have satisfied the EH36 steel grade. For the each-side one-pass welding joint with a heat input of 130 kJ/cm,  $\sigma_{E-60}$  is more than 10 kgf-m at any notch position. The preheating temperature

for crack prevention has been confirmed to be below 0°C by the Y-groove restraint test. (Author abstract) 5 refs.

**080662 PROPERTIES OF 390- AND 415-MPA YIELD STRENGTH STEEL PLATES WITH GOOD TOUGHNESS IN LARGE HEAT INPUT WELDED JOINTS.** Ship structural 390 MPa yield strength (YP40 kgf/mm<sup>2</sup>) steels and an offshore structural 415 MPa yield strength (YP 42 kgf/mm<sup>2</sup>) steel were developed to assure good low temperature toughness in large heat input welded joints. They were produced using MACS (Multipurpose accelerated cooling system) with low N and a small amount of Nb and REM-Ti addition for the YP 415 MPa steel. Tensile, Charpy impact and fracture mechanics tests proved that the steel plates and their welded joints made by electro-gas welding and one-side one-pass submerged arc welding with heat inputs of 147 to 274 kJ/cm had sufficient properties for ship and offshore structures. (Author abstract) 8 refs.

**080663 DEVELOPMENT AND MANUFACTURE OF LOW P<sub>CM</sub> HIGH TOUGHNESS STEEL PLATES FOR API 5L-X60 UO PIPE.** A steel was developed and applied to the production of plates for UOE line pipes which are used to transport sour oil in the North Sea. The steel plates 22.2 to 38.1 mm thick were made of API 5L-X60 and weigh 50,000 tons in total. The most critical and the most difficult requirements to be met follow: The P<sub>CM</sub> which is an indicator of the susceptibility to weld cracking should be as low as 0.150% for plates 22.2 and 23.8 mm thick. These requirements were unable to be satisfied by the ordinary manufacturing process. Only the thermo-mechanical control process (TMCP) and the fine steel making process were able to do it. The present paper describes the details of the steel plate manufacturing processes and the properties obtained. (Author abstract) 5 refs.

**080664 MECHANICAL PROPERTIES OF 9% NI STEEL PLATES PRODUCED FROM CONTINUOUSLY CAST SLABS.** From a low-P (0.006% max), low-S(0.002% max) continuously cast slab, 9% Ni steel plates for LNG storage tanks were produced by the direct quenching and tempering process (MACS-T) and reheat-quenching and tempering process (RQ-T). In the MACS-T process, slab-reheating and finish-rolling temperatures were increased in order to increase ductile fracture energy by decreasing the amount of precipitated austenite. Reliability for LNG storage tanks was examined by conducting fracture toughness tests on these steel plates and their welded joints. As a result, it was shown that these steel plates and their welded joints had good crack initiation and arrest toughness. (Author abstract) 12 refs.

**080665 DEVELOPMENT OF HIGH TENSILE STRENGTH STEEL PLATE FOR HIGH HEAT INPUT WELDING.** Low alloyed high tensile strength steel plates for arctic offshore structures and cryogenic storage tanks are required to have high toughness in high input welds. We have already reported that Ti-Ca treated 490 N/mm<sup>2</sup> class high tensile strength steel plate have high

toughness in high heat input welds (heat input  $\leq 10$  kJ/mm). However, steel plates with high toughness in higher heat input welds (heat input  $\geq 10$  kJ/mm) are required. Investigations have been carried out to study the effect of micro alloying elements (Al, B and N) on toughness of high heat input welds (heat input  $\geq 10$  kJ/mm) of Ti-Ca treated 490 N/mm<sup>2</sup> class high tensile strength steel plates. From these results, it is concluded that the Ti-B-Ca treated low Al medium N steel could meet the specification. (Author abstract) In Japanese. 7 refs.

**080667 DEVELOPMENT OF TMCP THICK PLATE FOR SKYSCRAPERS.** The rise of welding cost which stems from the increasing carbon equivalent of steel plate is getting in the way of the application of very thick steel plates in skyscraper construction. To clear away this obstacle in manufacturing 100 mm-thick SM 50 B steel plates, we tried to introduce the TMCP, which consists of special rolling and accelerated cooling, in place of the conventional normalizing process. The application of the TMCP brought about the noticeable improvement of the weldability and toughness of weld heat affected zone. For instance, the preheat temperature at welding seemed to be decreased more than 75°C under the conventional one. (Edited author abstract) In Japanese. 7 refs.

**080668 BEHAVIOUR OF BOLTED JOINTS OF CORRUGATED STEEL PLATES.** Fifteen tests of lap joints of 3, 5 and 7 mm thick corrugated steel plates were conducted under uniform moment conditions to establish the moment-rotation behavior of the joints. Low, medium and high torques were used to tighten the bolts. Laps were made with 2, 3 and 4 bolts per complete corrugation. The moment-curvature diagrams for plate specimens were established theoretically and verified experimentally. The lap joint tests show conclusively that correct and incorrect laps exist. Correct lap joints are those in which no bolt is placed on the tension side of the lap at the location where the plates tend to separate when moments are applied, i.e., where prying occurs. These laps are correct for either direction of bending. In incorrect lap joints, tearing occurs transverse to the span from the edge of the bolt holes located on the tension side where prying occurs. This results in reduced ductility. (Edited author abstract) 2 refs.

**080669 TEMPER EMBRITTLEMENT AND HYDROGEN EMBRITTLEMENT IN Cr-Mo STEEL PLATES FOR PRESSURE VESSELS.** It has been pointed out that the mechanical properties of Cr-Mo steels for pressure vessels were deteriorated by hydrogen at lower temperature after shutdown. Recently it has also been demonstrated that hydrogen embrittlement was accelerated by temper embrittlement, which occurred

during operation at elevated temperatures. The interaction between these two embrittlements in 3Cr-1Mo steel has been investigated in this study. It was found that the degree of hydrogen embrittlement of temper embrittled materials was larger than that of unembrittled material. In addition, the ratio of intergranular fractured surface area to total surface area was increased with the increase of hydrogen embrittlement and/or temper embrittlement. (Author abstract) 5 refs.

**080670 LIMIT STATES DESIGN CONSIDERATIONS FOR GUSSET PLATES.** The paper discusses the design considerations that must be made when designing for ultimate strength, specifically, utilizing the limit states design formulation. Thus, limit states design models are described for tension and compression applications of gusset plates, although it is noted that much more research is needed before the criteria for compression can be considered as complete. Of particular interest are the second-order deformation effects in gusset plates; these are recent findings in experimental studies. It is demonstrated how load application and direction as well as type and orientation of the boundary connections have a major influence on the strength and behavior of these plates. A final summary itemizes the design checks that should be made. (Edited author abstract) 12 refs.

**080674 UOSNOST OCELOVYCH DOSIEK KOTVENYCH DO BETONOVYCH DOSIEK.** [Bearing Capacity of Steel Plates Anchored in Concrete Elements]. An engineering solution of the connection between the supporting concrete structure and other elements by steel plates anchored in concrete is presented. Steel plates are loaded by a vertical force  $F_d$  and bending moment  $M_d$ . Anchorage is made by reinforcing bars welded to the steel plate. Steel elements (corbels) supporting external walls are attached to the plate. An experimental investigation of bearing capacity was conducted for various models of anchorage. Due to the vertical force  $F_d$  acting on eccentricity  $e_d$  horizontal and vertical displacements occur. The character of the stress-strain relationship is affected by the ratio of eccentricity  $e_d$ , and the arm of forces  $z$ , quality of the concrete element and by diameter, length and arrangement of the anchorage bars. (Edited author abstract). 3 Refs. In Czech.

**080676 LEVY TYPE SOLUTIONS FOR SYMMETRICALLY LAMINATED RECTANGULAR PLATES USING FIRST-ORDER SHEAR DEFORMATION THEORY.** Closed-form solutions for the bending case of the classical laminated plate theory and the first-order shear deformation theory were previously developed for two types of simply supported boundary conditions and certain lamination schemes. These served as excellent references for comparison by numerical analysis. Such closed-form solutions of the first-order shear deformation theory for composite laminates with other types of boundary conditions are not reported in the literature. The study deals with the development of Levy-type solutions originated by Levy (1899) and approached in this paper in conjunction with the state-space concept. The analysis concerns the solution of the first-order transverse shear deformation theory of symmetrically laminated rectangular plates with two opposite edges simply supported and the remaining edges subjected to a combination of free, simply supported, and clamped boundary conditions. 10 refs.

**080679 VPLYV OKOLITEHO ZATAZENIA POL-PRIESTURU NA DOSKOPEPASY S PRIHLIAD-NUTIM NA REOLOGICKE VLASTNOSTI MATERIALOV DOSKY A PODLOZIA.** [Effect of Nearby Loading of Halfspace on Plate Strips with Regard to Rheological Properties of Plates and Subgrade Materials.] This paper deals with the contact problem of a plate strip and halfspace under the action of a nearby loading of the halfspace. The case of the plane strain is considered, the materials both of the plate and the halfspace having time-dependent properties. It is assumed that the plate and the halfspace represent homogeneous and isotropic bodies the creep of which is governed by different constitutive relations of the linear hereditary type. The problem is formulated by integral-differential systems of equations of the plate strip bend and vertical displacement of the halfspace boundary in which the unknown function of contact stress is determined from the conditions of plate strip balance and from the contact condition of the plate strip and halfspace in each point of the footing bottom interval. The solution is demonstrated by two numerical examples. (Edited author abstract) 21 Refs. In Czech.

**080680 THERMAL STRESSES IN A SEMI-INFINITE PLATE WITH A HOLE DUE TO TEMPERATURE DISCONTINUITY ON ITS STRAIGHT EDGE.** A steady-state thermal stress problem is solved for a semi-infinite plate with a thermally insulated circular hole when a finite segment of its straight edge is heated with a prescribed temperature. Both the temperature and stress solutions are constructed by summing the temperature and stress fields due to point heat sources and loads distribution inside the hole. The intensity of heat sources and loads are determined from the boundary conditions on the hole using the least squares method. The boundary conditions on the straight edge are satisfied exactly. Extensive and detailed numerical calculations are carried out to clarify the effects of the length of heated segment and the distances of the hole from the straight edge and the center of the heated segment of thermal stress concentration. The results show the power and flexibility of the method. (Author abstract) In Japanese. 11 Refs.

**080682 SIMPLIFIED ANALYSIS OF THE EFFECT OF TRANSVERSE SHEAR ON THE RESPONSE OF ELASTIC PLATES TO IMPACT LOADING.** This investigation deals with the problem of transverse impact on an elastic plate for which the effect of deformation due to transverse shear cannot be neglected, e.g. a thick plate or one reinforced with aligned fibers in its plane. Closed-form solutions have been obtained, after minor approximation, to determine the deflection and bending moment at the point of impact. It is shown that a single parameter can describe the influence of transverse shear on the impact force as well as on the deflection and bending moment at the impact point. Finally, numerical results are presented to show that the influence of shear on deflection is much smaller than that on impact force or bending moment. (Edited author abstract) 18 Refs.

**080683 STRESS CONCENTRATION AROUND A PART-THROUGH HOLE WEAKENING A LAMINATED PLATE.** A quasi-three-dimensional-elasticity type theory, based on the assumptions of transverse inextensibility and layerwise constant shear-angle, is presented, in the context of an assumed quadratic displacement potential energy approach, for analyzing an edge-loaded laminated plate weakened by the presence of a part-through hole. Numerical results, obtained using the C-type triangular finite element, indicate the existence of severe cross-sectional warping in the vicinity of the hole and plate boundaries. Furthermore, the three-dimensional nature of the stress concentration factor in the neighborhood of the hole boundary is clearly exhibited. Besides, very high stress concentration factors are found in the layer weakened by the part-through hole. The numerical results presented should serve as bench-mark solutions for future comparisons. (Author abstract) 31 Refs.

**080684 EFFECTIVE BREADTH PROBLEMS BY AN EIGENFUNCTION APPROACH.** The problem of effective breadth of a stiffened panel with two different edge or support conditions, namely (i) stress-free edges and (ii) displacement restrained edges, has been solved for the first time, in this paper, by the eigenfunction approach to the end problem of semi-infinite strips. It is shown that these two edge conditions lead to complex eigenvalue problems and thus the plane-stress problem of the plating cannot be solved by the classical methods which have been hitherto successfully used to obtain the estimates of effective breadths for the two other possible mixed edge conditions, namely, (i) vanishing direct stress and tangential displacement and (ii) vanishing normal displacement and shear stress. It is brought out that this end eigenfunction formulation, using a generalized orthogonality of Papkovitch, provides a general analytical framework for the stress field problems of stiffened panels in bending. **080686 ANALYSIS OF THERMAL STRESSES IN PLATES WITH BOUNDARY ELEMENT METHOD.** In this paper an integral formulation, dealing with thin plates under thermal load, is presented. The field equation is decomposed into two harmonic equations which are formulated in an integral form by application of Green Second Theorem. The domain integrals which appear in the formulation will be transformed into equivalent boundary integrals, in particular distributions of temperature as well as in a general case where this is known only in a discrete form. In this way, the main advantage of the boundary element method of reducing the dimensions of the problem, is preserved. Two examples will be studied to prove the efficiency of the formulation proposed. (Author abstract) 13 Refs.

**080687 NONLINEAR STATIC ANALYSIS OF RECTANGULAR PLATES ON ELASTIC FOUNDATIONS BY THE ORTHOGONAL POINT COLLOCATION METHOD.** In this paper, the simplicity and good accuracy of this orthogonal point collocation method is demonstrated for the solution of some geometrically nonlinear problems of moderately large deflections of rectangular plates subjected to static loads. Von Karman-type governing equations are employed. Clamped and simply supported plates with immovable inplane conditions at the edges are considered. Plates which are simply supported at two opposite edges and clamped at the other two edges are also analyzed. Winkler and Pasternak models of elastic foundation are used. The present results agree quite well with the available ones. New results are presented for orthotropic plates resting on Winkler and Pasternak foundations. (Edited author abstract) 18 Refs.

**080688 SOLUTION OF PROBLEMS OF THE BENDING OF ORTHOTROPIC PLATES WHICH YIELD IN TRANSVERSE SHEAR.** The use of plates and shells made of composites in different areas of technology requires that they be designed on the basis of refined models which take into account their low stiffness in transverse shear. Various such models have been presented. The authors propose an approach to the solution of a class of problems concerning the stress state of rectangular orthotropic plates subjected on their faces  $z = \pm h/2$  to normal loads. They allow for both transverse shear strain and transverse normal stresses. 10 Refs.

**080689 ON THE ANALOGUES RELATING PLANE PROBLEMS OF COUPLE-STRESS THEORY AND REISSNER'S PLATE THEORY.** The analogous relations between the plane problems of couple-stress theory and REISSNER'S theory are established. Then the analytical and numerical approach in REISSNER'S plate theory can be applied to the couple-stress theory. By means of analogous relations we can predict that the state of stress for the plane problem of the couple-stress theory can be also composed by three elementary parts: the classical elastic problems corresponding to the state of stress as the couple-stress constant  $l$  approaches to zero, the corrective state of stress and the

boundary layer effect. Similar to the asymptotic expansion the solutions for the couple-stress theory are obtained. 5 refs.

**080690 FINITE NOTCHED PLATE STIFFENED BY A SMALLER CIRCULAR DISK.** In this paper, the solution of a finite notched plate stiffened by a smaller circular disk is investigated by using a partitioning plan combined with the modified generalized variational method. It is assumed that the notched plate and the disk are both under the condition of generalized plane stress. The region under consideration is then divided into three subregions and complex potentials are introduced in each subregion, whose coefficients are determined from the stationary conditions of a proposed functional. Numerical results for the effect of the disk radius on the stress concentration factors of the elliptic notch are shown in the figures. The stress distribution between the notched plate and the disk are given in a table. (Author abstract) 7 refs.

**080694 DYNAMIC STRESS ANALYSIS OF PLATES OF DIFFERENT KINDS OF MATERIAL.** Structures of machine parts subjected to impact load often suffer unexpected damage, which is remarkably different from that observed in static cases. Generally, the reflection and interference of stress-wave play an important role in dynamic cases, and it is desirable to study the time variation of the stress distribution, and especially the value of dynamic stress concentration factors around the bound-

aries of different kinds of materials. Hence, we analyzed stress propagation and dynamic stress concentration phenomena around the boundary of different kinds of materials in a plate by utilizing the strain gage method, the dynamic photoelastic method and also the finite element method. We found that two-dimensional dynamic stress concentration factors obtained by the present three methods are in general agreement and if the ratio of  $E_2$  (young's modulus for the different materials)/ $E_1$  (young's modulus for the matrix) is small, the dynamic stress concentration factor is small, but the position of maximum stress occurs at the circular boundary of the matrix. **080697 QUADRILATERAL HYBRID STRESS PLATE ELEMENT BASED ON NATURAL STRAINS.** Hybrid stress-based finite elements have been shown to model plate bending behavior accurately and in some cases lead to better stress and displacement results than  $C^0$ -based finite elements that employ reduced/selective integration schemes. A procedure for the development of a hybrid stress plate bending finite element is outlined. In the formulation of the element stiffness matrix, the intra-element displacement interpolation is referenced with respect to curvilinear coordinates. The form of the strain-displacement equations for the special case of an element with isoparametric distortion utilizing a bilinear interpolation is used. It is expected that by referring strains to finite element curvilinear coordinates, element performance will be improved under arbitrary isoparametric distortion. 5 refs.

**080698 THEORETICAL MODELLING OF LAMINATED COMPOSITE PLATES.** Formulation of appropriate governing equations, simpler than the three-dimensional equations of elasticity yet capable of predicting, fairly accurately, all important response parameters such as stress and strain, is attempted in modelling a structural component. Several theoretical models are available in the literature for the analyses of plates. The emergence of fibre-reinforced plastics as an attractive form of structural construction added a new complexity to the modelling considerations of lamination by requiring the estimation of the interlaminar stresses and strains. In this paper, modelling considerations of laminated composite plates are discussed. The classical laminated plate theory and higher-order shear deformation models are reviewed to bring out their interlaminar stress predictive capabilities, and some new modelling possibilities are indicated. (Author abstract) 31 refs.

**080699 STUDY ON AN IDENTIFICATION METHOD OF RESIDUAL STRESSES IN A PLATE BY INVERSE ANALYSIS.** Inverse analysis using the boundary element method is considered theoretically very useful for the quantitative estimation of complicated stresses in a solid material induced by machining, heating and so on. However, a more refined fundamental consideration is still needed for a reliable evaluation of the stresses. In order to find a more practical estimation method, the authors have carried out several numerical simulations by using rectangular plate models with residual stresses induced by spot heating in the plate. They have also made an improved identification program of the boundary element method. Through typical calculations using this program, they found that unknown residual stress distribution in the plate was identified with enough accuracy from input data of the boundary displacements and tractions. (Author abstract) In Japanese. 9 refs.

**080700 ANALYSIS AND MEASUREMENTS OF RESIDUAL-STRESS REDISTRIBUTION DUE TO MATERIAL REMOVAL IN A PLATE.** Residual-stress redistribution caused by making a full-depth hole in a plate with biaxial residual stresses was elastically calculated using the Finite Element Method (FEM). The initial residual stresses were introduced into each finite-element through the intermediary of the most suitable eigen-strain distribution in such a way as to accord with the X-ray residual stresses measured prior to the material removal. A new calculation method is also proposed which removes at a time all the finite-elements of the removal-area in the FEM analysis, in contrast to the conventional method in which the elements are removed one by one. The analytical results of residual-stress redistribution were in good agreement with the X-ray residual stresses measured after drilling with an end mill, in the plate with residual stress induced by welding or by water-cooling. These results show that the residual stress change due to the material removal occurs markedly in the vicinity of the removed place. (Author abstract) 7 refs. In Japanese.

**080702 OPTIMAL VERSION OF REISSNER'S THEORY.** An improved version of Reissner's theory, called Optimal version, is proposed in the case of homogeneous and isotropic plates with any edge boundary conditions. It differs from the classical theory by the value of the transverse shear deformability factor and by the boundary conditions. Three-dimensional displacement and stress distributions expressed in terms of the Optimal version are given for any point of the plate, whether within the plate itself or in the neighborhood of its edge. It is proved that these distributions are second-order approximations of the exact three-dimensional solution - relative

error  $O(h^2/L^2)$ . Consequently, Optimal version is a second-order theory; therefore it is better than Kirchhoff-Love's theory. (Author abstract). 13 Refs.

**080703 STRESS ANALYSIS OF CRACKS OF ARBITRARY SHAPE IN FINITE PLATE SUBJECTED TO UNIFORM TENSION.** Using finite element method (FEM) the stress field and the stress intensity factors at the crack tips are obtained for the cracks of arbitrary shape in a plate of finite width subjected to uniform tension. Different crack geometries that are considered are central angled crack, crack in the form of an arc of a circle, angled edge crack, and the angled edge crack at one edge and a straight crack at the other edge. The conclusions drawn are: (a) The finite element analysis, using singularity elements, can be used to analyse the problems involving edge cracks with arbitrary geometry. (b) The linear extrapolation method to evaluate a crack tip SIF yields better results than curvilinear extrapolation when compared with analytical solutions for cracks in plate of infinite width. (c) For predicting the path of crack extension all the three fracture criteria are in good agreement with each other. They predict the paths of crack extension lie within the experimentally observed scatter range. 8 Refs.

**080705 BOUNDING APPROACH TO THE BIFURCATION POINT OF ANNULAR PLATES WITH NONASSOCIATED FLOW LAW SUBJECTED TO UNIFORM TENSION AT THEIR OUTER EDGES.** A boundary approach based on numerical procedure is developed to investigate the bifurcation behavior of nonuniformly stressed solids obeying the nonassociated flow law. An improved lower bound to the bifurcation point is determined by optimizing a positive parameter  $r$  in the linear comparison solid. Accuracy of the obtained lower bound is examined by the upper bound analysis. The nonaxisymmetric bifurcation behavior of pressure-sensitive and dilatant annular plates subjected to uniform tension at their outer edges has been analyzed. The results indicate that the optimization of the parameter  $r$  is essential in achieving considerable improvement of the lower bound to the bifurcation point. Nonassociatedness always destabilizes the deformation. Furthermore, the effect of work hardening rate and yield stress on the bifurcation behaviors has been clarified. (Author abstract). 14 Refs.

**080706 ISOPARAMETRIC ECCENTRICALLY STIFFENED PLATE BENDING ELEMENT.** An 8 noded, eccentrically stiffened, plate bending element is introduced. The formulation allows for any number of stiffeners arbitrarily orientated within a plate element without disturbing their individual properties and positions. This is a distinct improvement over conventional lumped stiffener modeling and equivalent orthotropic plate theory and considerably simplifies the modeling of stiffened structures. A technique is also presented which

transforms stiffener positions defined in the global cartesian system to the local, isoparametric coordinates of the plate element which contains the given stiffener. Several examples are given which demonstrate the usefulness of the element. (Author abstract). 11 Refs.

**080709 ANALYSIS OF CONTINUUM BY THE INTEGRATED FORCE METHOD.** The novel formulation termed the integrated force method (IFM) has been established for finite element discrete analysis. In this paper we have extended the IFM for the analysis of continuum taking circular plate as the example. The primary variables of the analysis are moments. All the continuum equations (equilibrium equations and compatibility conditions) in the field and on the boundary are obtained in moments from the stationary condition of the variational functional of the IFM. A new stress function required for the functional is defined. The variational functional yields the known equations along with the novel boundary condition identified as the boundary compatibility condition. The moment solution for the plate problem is obtained without any recourse to displacements either in the field or on the boundary. From moments, displacements are obtained by integration and boundary displacement continuity conditions. The IFM solution and boundary compatibility conditions are verified using S.P. Timoshenko's work and finite element displacement method. (Author abstract) 16 Refs.

**080710 REFINED ANALYSIS OF LAMINATED PLATES BY FINITE ELEMENT DISPLACEMENT METHODS - I. FUNDAMENTALS AND STATIC ANALYSIS.** This and a companion paper present a local finite element model based on a refined approximate theory for thick anisotropic laminated plates. The three-dimensional problem is reduced to a two-dimensional case by assuming piecewise linear variation of the in-plane displacements  $u$  and  $v$  and a constant value of the

lateral displacement  $w$  across the thickness. By using a substructuring technique the present model is demonstrated to be practical and economical. The static bending stresses, transverse shearing stresses and in-plane displacements are predicted in the present paper. (Edited author abstract) 18 Refs.

**080713 ASM SOLUTION OF STIFFENED SECTOR PLATES.** This study extends the application of the Analytical Strip Method (ASM) of solution to stiffened sector plates. The plate is idealized as a system of horizontally curved plate strips and beam or rib segments rigidly connected to each other. The behavior of the system is derived by imposing the edge and continuity conditions on the closed-form solutions of the individual plate strips and beam elements. The method is applicable to plate-stiffener systems subjected to various loading conditions and with different boundary conditions along the straight and circular edges. The advantage of the ASM solution over the 'equivalent' orthotropic plate substitute is that unequally spaced stiffeners and stiffeners of different cross-sectional properties can be introduced in the solution. Results are presented for stiffened sectors with different edge and loading conditions. (Author abstract) 18 Refs.

**080714 EFFECT OF CRACK ON RIDGE OF PLATE STRUCTURE.** The present study is concerned with the membrane and bending stresses induced in a folded plate in the presence of a crack at the ridge of the folded plate. The classical method of solving dual integral equations by converting them into singular integral equations is applied for determination of stresses in a folded plate structure which is weakened by a crack. The crack is located along the ridge of the folded plate structure whose behavior is governed by the coupled set of equations pertaining to bending and stretching deformations. The presence of the crack leads to the formation of a system of dual integral equations with Cauchy

kernels. These are solved numerically by applying the Chebyshev integration formula in conjunction with certain collocation techniques. (Author abstract) 12 refs.

**080716 3D STRESS FIELD AT THE INTERSECTION OF A HOLE AND A FREE SURFACE.** It is well known that at the vertex of a sector plate, in stretching and in bending, unbounded stresses may occur for certain vertex angles. The author in this paper investigates the analytical stress field in the neighborhood of the intersection of a hole and a free boundary. Utilizing the form of a general 3D solution, which was constructed in a previous paper, he recovers the explicit displacement and stress fields in this neighborhood. Moreover, the analysis shows the complementary solution to be proportional to  $\rho^{\alpha-2}$ , where  $\alpha$  is independent of the Poisson's ratio  $\nu$ . Interestingly enough the first root is exactly that obtained by the William's solution for a 90 deg corner with free-free of stress boundaries. (Edited author abstract) 6 refs.

**080719 FATIGUE LIFE AND CRACK THROUGH THICKNESS BEHAVIOR OF A SURFACE-CRACKED PLATE: (FOR THE CASE OF TENSILE LOAD).** A fatigue crack Propagation test was carried out on HT80 and mild steel, and crack through thickness behavior was examined in detail, both experimentally and analytically. The major results are as follows. 1) The fatigue crack shape before penetrating the whole thickness is almost semicircular, and the measured aspect ratio is larger than the value obtained by calculation using the K value proposed by Newman-Raju. 2) It is found that the crack growth behavior on the back surface, i.e., the growth behavior of cracks after they have run through the plate, is unique and can be divided into three stages, a, b and c.

3) The fatigue crack growth rate at the stage b is constant for a wide range and is in direct proportion to the n-th power of the range of stress,  $\Delta\sigma$ . 4) A new model has been proposed to evaluate the K value after cracking through the plate thickness. 5) The K value proposed by the authors makes it possible to explain quantitatively the particular behavior of cracks after they have run through the plate. (Author abstract) 10 refs.

**080720 DYNAMIC RESPONSES OF ORTHOTROPIC PLATES UNDER MOVING MASSES.** The problem considered is that of heavy masses moving on lightweight rectangular plates of orthotropic materials, slated for use in space structures. The dynamic equation of motion for orthotropic plates which contains singularities in both space and time variables is first presented. The response is expressed as a summation of double series of eigenfunctions. The equation of motion is transformed into an integro-differential equation for modal amplitudes using the Green's function. The effect of orthotropy on natural frequencies and dynamic responses is demonstrated. (Edited author abstract)

**080721 DAMPED RESPONSE OF THIN PLATES TO STEP LOADS INCLUDING GEOMETRIC NONLINEARITY.** This paper presents an approximate solution of the large deflection damped response of thin isotropic circular and rectangular plates subjected to step loads. Simply-supported and clamped plates with movable and immovable inplane conditions are considered. Von Karman-type equations are employed in terms of the transverse deflection and the stress function. The deflection is approximated by a one-term spatial shape function and Galerkin's method is used to obtain the differential equation for the central deflection. (Edited author abstract) 6 refs.

**080722 LARGE DEFLECTION ANALYSIS OF ORTHOTROPIC PLATES - ADAPTATION OF COAN'S METHOD.** The problem considered is the elastic large deflection analysis of thin, rectangular, specially orthotropic plates with two axes of symmetry. Coan's method for allowing the prescription, for isotropic plates, of the in-plane tensile or compressive loading along two opposite edges, is adapted to deal with orthotropic plates. This analysis has been incorporated into an existing computer program (ELDAROP), and the results agree well with previous work on isotropic plates. Results are given for the post-buckling of square orthotropic plates under uniaxial in-plane compression. These confirm that if the unloaded edges are maintained straight, the post-buckled stiffness increases, and this effect decreases as the modular ratio increases. (Author abstract) 9 refs.

**080723 BUCKLING AND VIBRATION OF SHEAR DEFORMABLE PRISMATIC PLATE STRUCTURES BY A COMPLEX FINITE STRIP METHOD.** A finite strip method is presented for the determination of buckling stresses and natural frequencies of vibration of prismatic plate structures assembled from plate flats, which generally are laminates of fibre-reinforced composite material. The finite strip method is of the single-term type, corresponding to the assumption of sinusoidal longitudinal spatial variation of displacement and force quantities. Anisotropic material behaviour and applied in-plane shear stress are accommodated by expressing the strip displacement field in terms of complex quantities. The out-of-plane properties of plate flats are based upon the use of first-order shear deformation plate theory. A family of finite strip models is described and a sub-structure

turing procedure is utilized to reduce the size of the eigenvalue problem. Presented numerical results reveal the high accuracy and good convergence characteristics of the method, as well as indicating the influence of through-thickness shear effects in a range of circumstances. (Author abstract) 27 refs.

**080724 FINITE ELEMENT TRANSIENT DYNAMIC ANALYSIS OF ISOTROPIC AND FIBRE REINFORCED COMPOSITE PLATES USING A HIGHER-ORDER THEORY.** A higher-order shear deformable  $C^1$  continuous finite element is developed and employed to investigate the transient response of isotropic, orthotropic and layered anisotropic composite plates. The governing ordinary linear differential equations are integrated using the central difference explicit time integration scheme. A special mass matrix diagonalization scheme is adopted which conserves the total mass of the element and includes the effects due to rotary inertia terms. Numerical results for deflections and stresses are presented for rectangular plates under various boundary conditions and loadings. The parametric effects of the time step, finite element mesh, lamination scheme and orthotropy on the transient response are investigated. The numerical results are compared with those obtained by solving the same problems using the Mindlin plate element. (Edited author abstract) 24 refs.

**080725 ANALYTICAL STRIP METHOD OF SOLUTION FOR STIFFENED RECTANGULAR PLATES.** The recently developed analytical strip method of solution for bending of orthotropic rectangular plates is extended in this study to stiffened rectangular plates. In this method, the plate is idealized as a system of plate strips and beam segments rigidly connected to each other. The behavior of the system is derived by imposing the edge and continuity conditions on the closed form solution of the individual plate strips and beam elements. The analytical strip method possesses the advantages of the semi-analytical finite strip method but avoids the polynomial representation and minimization procedure associated with it. Numerical results are presented for stiffened and unstiffened rectangular plates for different edge and loading conditions. (Author abstract) 9 refs.

**080726 FINITE ELEMENT ANALYSIS OF A LAMINATED COMPOSITE PLATE SUBJECTED TO CIRCULARLY DISTRIBUTED CENTRAL IMPACT LOADING.** A two dimensional finite element analysis has been made for a fiber-reinforced composite laminate subjected to circularly distributed impact load which results, for example, from impacting the plate with a blunt-ended projectile. A finite element displacement model which includes the effects of transverse shear deformation and rotary inertia was used along with Hamilton's principle to derive the finite element matrices. Newmark's direct integration technique was used to integrate with respect to time. The interaction force between the projectile and the plate was calculated by using the Hertzian law of contact. Results for laminate deformations are shown to compare quantitatively with experimental results. Numerical values for stresses in the plate were calculated. (Author abstract) 16 refs.

**080730 TWO-LEVEL FINITE-ELEMENT METHOD FOR THIN PLATES SUBJECT TO CONCENTRATED LOADS.** A thin plate subject to concentrated loads (forces or moments) is customarily analyzed either by fine finite-element mesh or by singular elements. This paper recommends an alternative method using conventional finite elements with fine mesh and reducing the number of unknowns by interpolating the nodal displacements by means of the shape functions associated with the previously mentioned singular elements. New element matrices need not be generated and integration is avoided completely. Accurate results under the point load are achieved by a substantially reduced number of unknowns. Both concentrated forces and moments are considered. Accurate superelements can be formed to study plate systems. The procedure presented in this article results in substantially reduced computational effort, and is therefore specially suited for use on microcomputers. (Author abstract) 8 Refs.

**080731 CIRCULAR PLATE ON TENSIONLESS WINKLER FOUNDATION.** The equilibrium configurations of a thin circular plate supported on an elastic foundation of Winkler type that reacts in compression only are investigated. The plate is assumed to be subjected to eccentric concentrated load and moment as well as a uniformly distributed load. The solution is accomplished by minimizing the total potential energy of the system. As the coordinate functions for the displacement function of the plate, the free vibration mode shapes of the completely free plate are used by including a rigid translation and a rigid rotation. It is found out that the plate will lift-off when the foundation stiffness is low. The results for the plate on a conventional and tensionless Winkler foundations are given in figures and compared. **080734 LEAST-WEIGHT DESIGN OF PERFORATED ELASTIC PLATES FOR GIVEN COMPLIANCE: NONZERO POISSON'S RATIO.** In earlier papers, least-weight solutions were derived for perforated elastic plates having (a) a constant thickness, (b) a prescribed compliance value, and (c) a Poisson's ratio of zero value. It was found that the optimal solution for axially symmetric plates always consists of (i) unperforated regions or (ii) regions with ribs in only one (i.e. the radial) direction. In view of extensive recent study of this problem by mathematicians, the conclusions have important implications. In this paper, the foregoing results are extended to plates having a nonzero Poisson's ratio and the theory is illustrated with examples. Two solutions given are valid for both prescribed compliance and prescribed deflections. This investigation shows that in some unconstrained shape optimization problems the optimal solution cannot be obtained by conventional numerical (e.g. finite element) methods. (Edited author abstract) 20 refs.

**080739 OPTIMUM COMPLIANCE DESIGN OF STIFFENER LAYOUT OF THIN PLATE.** An optimum design technique of the stiffener layout which gives minimum compliance is developed. A thin plate with stiffeners is treated as an anisotropic plate of pseudo-continuous structure, and is discretized into the finite elements. The minimum compliance design subjected to the constant volume, in which the distributions of angles of the stiffener arrangement and the stiffener densities are varied, is determined by the recursive quadratic programming technique. By applying this design technique, the optimum layouts of the stiffener of the rectangular plate under some typical loading and supporting conditions are obtained. (Author abstract). 8 Refs. ## Theory

**080740 GENERAL ASYMPTOTIC APPROXIMATION TO THE NONLINEAR THEORY OF THIN ELASTIC PLATES.** The aim of this work is to construct

the general asymptotic nonlinear theory of thin elastic anisotropic plates undergoing large transverse deflection. We try to develop a scheme which determines the terms of any desired order in the asymptotic analysis. To this end, the nonlinear field equations on which an asymptotic expansion will be briefly recapitulated. Then, assuming an appropriate asymptotic expansion for the displacement vector and the stress tensor, the consistent  $n$ th order equations are derived. For the zeroth and first order approximations the maximum deflections are given. It is observed that first order corrections to the zeroth order solution are negligible in relatively thin plates. 3 refs.

**080741 ASYMPTOTIC THERMOELASTIC BEHAVIOR OF FLAT PLATES.** The present study is devoted to the dynamic behavior of a three-dimensional linearly thermoelastic flat plate. Specifically, a three-dimensional flat plate with small thickness is submitted to an arbitrary system of initial and loading conditions. The limits of the displacement, stress, and temperature fields as the thickness approaches zero are investigated. Thermoelastic behavior is characterized by a coupling between the mechanical equations of motion and the 'energy' equation. The limiting procedure is seriously affected by the presence of the coupling terms. The initial conditions are seen to play an essential role in the analysis. In particular, a change of initial condition generally occurs for the temperature field. A similar phenomenon appears in the homogenization of a thermoelastic composite. These concurring results seem to indicate that such shifts in initial data are closely linked to any kind of asymptotic problem for coupled systems. 12 refs.

**080742 ON THE SOLUTIONS OF CLAMPED REISSNER-MINDLIN PLATES UNDER TRANSVERSE LOADS.** The governing equations in the Reissner-Mindlin theory may be written in a form such that a small parameter  $\epsilon$  is involved. This parameter  $\epsilon$  depends on a combination of the shear modulus and the plate thickness. The governing equations are singularly perturbed with respect to  $\epsilon$ . However, as  $\epsilon$  approaches 0 one does recover the biharmonic equation of the classical plate theory. In a previous work of ours the behavior of solutions for clamped Reissner-Mindlin plates as  $\epsilon$  approaches 0 was studied and it was shown there that these solutions tend continuously, in various functional norms, to their corresponding solutions in the classical plate theory. This paper deals with two specific questions concerning the detailed dependence of these solutions on  $\epsilon$  as  $\epsilon$  approaches 0. We shall show the nonexistence of regular asymptotic expansions of the solutions in integral powers of  $\epsilon$  for general clamped Reissner-Mindlin plates. We shall also construct an exact solution for a circular plate which exhibits dependence on fractional powers of  $\epsilon$ . This latter solution shows a boundary layer phenomenon, decaying away from the boundary, often encountered in singular perturbation problems. (Author abstract) 8 refs.

Assifi, Thomas C. (EDS, Southfield, MI, USA); Yen, David H.Y. *Q Appl Math* v 45 n 4 Dec 1987 p 679-690.

**080743 THICKNESS EFFECT ON THE SPECTRAL PROPERTIES OF THICK PLATES.** This paper shows the effect of plate thickness on the spectral properties of the stiffness matrix which is obtained from finite element representation. The results confirm the very stiff properties associated with the strain energy based on Reissner and Mindlin theories in the case of thin plates. On the other hand, the Bergan and Wang approach converges to exactly the classical thin plate solution as the thickness decreases. (Author abstract) 10 refs.

Hassan, Kamal (Ministry of Higher Education, Cairo, Egypt). *Commun Appl Numer Methods* v 4 n 1 Jan-Feb 1988 p 1-4.

**080744 STIFFENED PLATES SUBJECT TO TRANSVERSE LOADING.** The generalized conditions under which stiffened plates can be approximated as a two-dimensional continuum are investigated and identified. A simplified set of constitutive equations defining the full class of problems described above, subject to elastic behavior, are then obtained by making suitable assumptions. The significance of these assumptions is investigated under a wide range of conditions, and the results calculated for typical problems using the simple theory. The simple theory is then amended to allow consistently for the effects due to Poisson's ratio in the stiffeners. A study of the resulting equations indicates that whilst the normal assumption of centroidal neutral axes is justified under all conditions, the additional strain energy generated in the stiffeners can be significant, and that under the assumption of centroidal neutral axes this is readily included in the formulation without penalty. (Edited author abstract) 19 refs.

**080745 INDIRECTLY DERIVED INTEGRAL EQUATION SYSTEM FOR SIMPLY SUPPORTED REISSNER PLATES.** Three new indirectly derived integral equations for Reissner plates with simply supported boundaries are presented. Layers of statical and of geometrical singularities are used to generate integral equations suitable for numerical applications. Based on investigations of the spectra of integral operators, some criteria for the choice of the singularities, and thus of adequate integral equations, are known in the case of plane elastostatic but not, as yet, for the equations presented here. Therefore, a known fact is used as a criterion: The numerical solution of integral equations of the first kind can be problematic. 9 refs.

Antes, H. (Ruhr Univ Bochum, Bochum, West Ger). *Mech Res Commun* v 13 n 2 Mar-Apr 1986 p 63-69.

**080746 HYBRID FINITE STRIP ANALYSIS OF MULTILAYER LAMINATED PLATES.** A rigorous analysis of the behavior of multilayer laminated plates must take into consideration the heterogeneity through the thickness of the laminate. As it well-known, negligence of the through-thickness effect by the classical laminated plate theory may result in an unreliable estimation of the stress distribution in the laminates. (Edited author abstract) 24 refs.

**080748 MIXED FINITE ELEMENT FORMULATION FOR REISSNER-MINDLIN PLATE THEORY: UNIFORM CONVERGENCE OF ALL HIGHER-ORDER SPACES.** A new mixed finite element formulation of Reissner-Mindlin theory is presented which improves upon the stability properties of the Galerkin formulation. General convergence theorems are proved which are uniformly valid for all values of the plate thickness, including the Poisson-Kirchhoff limit. As long as the dependent variables are interpolated with functions of sufficiently high order, the formulation is convergent. No special devices are required. (Author abstract) 23 refs.

Hughes, Thomas J.R. (Stanford Univ, Stanford, CA, USA); Franca, Leopold O.P. *Comput Methods Appl Mech Eng* v 67 n 2 Mar 1988 p 223-240.

**080749 SIMPLE INFINITE ELEMENT FORMULATION OF A HIGHER-ORDER THEORY FOR UNSYMMETRICALLY LAMINATED COMPOSITE PLATES.** A higher-order theory which satisfies zero transverse shear stress conditions on the bounding planes of a generally laminated fibre-reinforced composite plate subjected to transverse loads is developed. The displacement model accounts for non-linear distribution of in-plane displacement components through the plate thickness and the theory requires no shear correction coefficients. A  $C^0$  continuous displacement finite element formulation is presented and the coupled membrane-flexure behaviour of laminated plates is investigated. The simple isoparametric formulation developed here is capable of evaluating transverse shears and transverse normal stress accurately by using the equilibrium equations. The accuracy of the nine-noded Lagrangian quadrilateral element is then established by comparing the present results with the closed-form, three-dimensional elasticity and other finite element available solutions. 14 refs.

Kant, T. (Indian Inst of Technology, Powai, India); Pandya, B.N. *Compos Struct* v 9 n 3 1988 p 215-246.

**080750 CONTRIBUTION TO PLATE THEORY.** In this contribution a method for obtaining refined theories of elastic plates is suggested. It is an iterative method in which the three-dimensional elastic theory is approximated by a plate theory within the prescribed accuracy. The first iteration of the order  $O(h^4)$ , where  $h$  is the thickness of the plate, gives a theory identical to the classical theory. The second iteration of the order  $O(h^6)$  gives for sufficiently smooth and slowly varied pressure function  $p$  the approximation identical to the Reissner or the Khatadadjan theories.

Franek, Alexander. *Z Angew Math Mech* v 68 n 4 1983 p T184-T185.

**080751 INVERSE PROBLEM SOLUTIONS VIA PLATE THEORY WITH APPLICATIONS TO POSITION AND FORCE SENSING.** Theory of plates is employed to solve inverse problems in elasticity with specific applications to position and force sensing. The term 'inverse problems' implies the determination of position, distribution and magnitude of loads applied by an object on an elastic element, if strains are known at several locations of the element. Both analytical and numerical methods are presented. The analytical method presented is limited to rectangular plates having two opposite edges simply supported and uniform distribution in the loaded region. Inverse problems for different types of loading conditions are solved and simulated by computer. By assuming that strains at some locations are known, computer simulation results obtained by both analytical and numerical techniques are compared with exact solutions. The results thus obtained are quite good. Finally, strains were measured to verify the inverse problem solutions. 5 Refs.

Lin, P.P. (Cleveland State Univ, Cleveland, OH, USA). *J Appl Mech Trans ASME* v 55 n 2 Jun 1988 p 489-491.

**080752 ON BOUNDARY ELEMENTS FOR REISSNER'S PLATE THEORY.** A direct boundary element formulation for Reissner's plate bending theory is reviewed and found to be also applicable to external problems in infinite plates. The formulation bears close resemblance with the standard plane strain boundary element implementation producing singular integrals of the same order. The numerical implementation is carried out for quadratic elements with complete freedom of local nodal positioning within the elements (i.e. continuous, discontinuous and semi-continuous elements are used, including the possibility of double nodes). Numerical examples are presented to demonstrate the accuracy of the procedure. (Author abstract). 17 Refs.

#### Thermoelasticity

**080757 THERMOELASTICITY OF A PLATE WITH A THIN-WALLED ELASTIC INCLUSION ALONG AN ARC OF A CIRCUMFERENCE.** The plane problem of heat conduction and thermoelasticity for a plate with a thin-walled elastic inclusion along an arc of a circumference is considered. The problem reduces to systems of two singular integrodifferential equations, whose solution is applicable for inclusions of arbitrary thermal conductivity and rigidity. An approach to the solution of these systems that differs from that of a

previous paper is proposed. A numerical analysis of the stress intensity coefficients is provided. (Edited author abstract) 9 Refs.

**080758 AXISYMMETRIC DYNAMIC STABILITY OF A BIMODULUS THICK CIRCULAR PLATE.** The object of the present paper is to investigate the dynamic stability of bimodulus thick circular and annular plates subjected to a combination of a pure dynamic bending and a uniform dynamic extensional stress in the plane of the plate. The Mindlin plate finite element model is established to solve the dynamic stability problems of an axisymmetric circular plate. A ring type element is chosen to approach the axisymmetric problem. The obtained results of the dynamic stability region are shown to be very good when compared with the closed form solutions for ordinary plates. The influences of various parameters on the dynamic stability boundary are studied. (Author abstract) 14 Refs.

**080759 FLEXURAL VIBRATION OF RECTANGULAR PLATES WITH POINT SUPPORTS.** Orthogonally generated polynomial functions are used in the Lagrangian multiplier method to study the free, flexural vibration problem of point supported, thin, flat, rectangular plates. The analysis applies to isotropic and specially orthotropic plates having any combination of clamped, simply supported or free edges with arbitrarily located point supports and to plates which are continuous over line supports parallel to the plate edges. Numerical results are presented for a number of specific problems, illustrating the accuracy and versatility of the approach, and which include natural frequencies and nodal patterns for a point supported plate which is continuous over two perpendicular line supports. (Author abstract) 36 Refs.

**080760 FUNDAMENTAL FREQUENCY OF TRANSVERSE VIBRATIONS OF RECTANGULAR PLATES WITH OVERSTEPPED VARIATION OF THE THICKNESS OVER A TRIANGULAR, CORNER-ADJACENT SUBDOMAIN.** The present study deals with the approximate determination of the fundamental frequency of vibration of the structural system by using polynomial co-ordinate functions which satisfy the boundary conditions. The inclusion in the co-ordinate function of an undetermined parameter  $\gamma$  as an exponent allows for minimization of the frequency coefficient when using the Rayleigh-Ritz methodology. 5 Refs.

**080761 HIGHER FREQUENCIES OF TRANSVERSE VIBRATION OF RECTANGULAR PLATES ELASTICALLY RESTRAINED AGAINST ROTATION AT THE EDGES AND WITH A CENTRAL FREE HOLE.** Numerical and experimental results for the transverse vibration of elastically restrained rectangular plates are compared showing large differences. One reason for this may be the fact that clamping induces in-plane compressive stresses at the outer edge while the inner boundary is stress-free. In other words, a non-uniform state of in-plane stress is generated and this may create severe variations of the frequency values. 2 Refs.

**080762 FREE VIBRATION AND FLUTTER OF LAMINATED QUADRILATERAL PLATES.** Free vibration and flutter of laminated quadrilateral plates with clamped edges have been investigated in this paper. Differential equations of motion in quadrilateral coordinates are derived and solved by the use of the integral equation technique. The results of free vibration analysis and flutter are compared with the values given in the available references. The behaviour of trapezoidal plates with different numbers of layers has been studied. (Author abstract) 10 Refs.

**080763 NONLINEAR RESPONSE OF ELASTIC PLATES TO PULSE EXCITATIONS.** The dynamic analogue of the Von Karman's equation is used to study the nonlinear response of elastic plates of square and circular geometry with simply supported and clamped-in boundary conditions and immovably constrained and stress-free edge conditions subjected to exponentially decaying (used for an adequate description of a blast load) cosine and exponential asymptotic step pulse excitations. Transformation of the dependent time function such that the solution of a linear system subjected to the same pulse function is used as an additional transforming function brings the time differential equation into a form in which the ultraspherical polynomial approximation technique can be applied to get the nonlinear response. This is compared with the digital solution obtained on the WIPRO-B-200 computing system by using the classical fourth-order Runge-Kutta method. (Author abstract) 7 Refs.

**080764 IMPULSIVE RESPONSE OF AN INFINITELY LONG PRESTRESSED THICK STRIP PLATE.** This paper is a study of the dynamic response of an isotropic plate strip to an impulsive load. The plate is of infinite length, simply supported along the edges, resting on a viscoelastic foundation, and is subjected to in-plane stresses parallel and perpendicular to the edges. The problem is studied on the basis of a plate theory, in which the effects of rotatory inertias and shear deformations are retained. Governing equations are solved by applying the methods of the Laplace transform with respect to time, and the Fourier transform with respect to a space variable. The displacement, the bending moment and the dynamic coefficient of the plate are calculated and shown graphically for several values of the initial stress parameters. (Author abstract) In Japanese. 7 Refs.

**080765 FREE VIBRATION OF CIRCULAR FOOTING ON ELASTIC FOUNDATIONS.** The free vibration of a circular plate on an elastic foundation is analyzed by using Vlasov's two-parameter model. The natural frequencies of the system under axisymmetric conditions are determined. In the region of the plate, the general solution is represented by Bessel functions. Modified wave equations are used to predict the harmonic motion of the elastic foundation. Since the region outside the plate is infinite, a reflected wave is not produced, thereby eliminating the need to consider a wave moving toward the plate. Finally, the effects of various parameters of the plate and the foundation of the natural frequencies system are discussed. (Author abstract) 6 Refs.

**080767 MUTUAL IMPEDANCE OF AXIALLY-SYMMETRIC MODES OF A CIRCULAR PLATE.** This paper presents an exact calculation of the mutual radiation impedance of axially-symmetric modes of a fixed at the edge circular plate. Linear and harmonic processes in respect to time have been considered and it has been accepted that the plate radiates acoustic waves into a lossless gas medium. Included here expressions for the mutual impedance in the form of single integrals have been adopted on the basis of several simplifying assumptions to numerical calculations for low and high frequencies of radiated waves. Achieved results are used in the analysis of the impedance and sound power radiated by a circular plate excited to vibrate by a known (from the assumption) superficial distribution of the exciting force. (Author abstract) 9 refs.

**080770 SOME DIDACTICAL AND SOME PRACTICAL REMARKS ON FREE PLATE WAVES.** It is recalled how wave equations can be generated from dispersion relations. The bending wave equation for thin plates including some higher-order terms is obtained by this general method and compared to the corresponding equation of Timoshenko. Further, the dispersion of free plate waves is derived in a concise and elementary manner without using a scalar potential and a vector potential for the displacements. Finally, as a matter of practical interest, exact and approximate expressions for the ratio of parallel to perpendicular displacements at a plate surface are calculated. Under favorable circumstances measurement of this ratio allows decomposing an observed wave into its quasi-longitudinal and bending components. (Author abstract) 12 refs.

**080773 FRAMEWORK FOR EFFICIENT FE VIBRATION SOFTWARE.** A new hybrid stress finite plate vibration capability, providing high accuracy for coarse-meshes is presented with a view to enhancing the behavioral characteristics of the standard hybrid FEM (finite element method). The software meets demands of the real-life user for reliable and cost-objective identification of a wide range of vibration modes. The FE matrices are constructed through the expedient of introducing a system of algorithms which provides an efficient and easily implemented capability that can be translated into any of the existing high level computing languages, viz. FORTRAN. The computational scheme enables the development of a large number of increasingly sophisticated elements from a single element module as easily as possible by providing it with a library of datasets. **080774 VIBRATION OF SYMMETRICALLY LAMINATED RECTANGULAR PLATES CONSIDERING DEFORMATION AND ROTATORY INERTIA.** An analytical study was conducted using the Galerkin technique to determine the natural frequencies and mode shapes for symmetrically laminated rectangular plates, considering the effects of shear deformation and rotatory inertia. Two different graphite-epoxy symmetric plates were used in the analysis and three different boundary conditions for each plate, simply supported, clamped, and two opposite sides clamped/two opposite sides simply supported, were considered. Convergence characteristics, comparison to classical results, and the effects of length to thickness ratios were investigated. The finding indicated that as the length to thickness ratios were reduced, shear deformation effects significantly lowered the natural frequencies. (Edited author abstract) 12 refs.

**080775 FREE VIBRATION ANALYSIS OF MINDLIN PLATES WITH LINEARLY VARYING THICKNESS.** A method based on the variational principles in conjunction with the finite difference technique is applied to examine the free vibration characteristics of

isotropic rectangular plates of linearly varying thickness by including the effects of transverse shear deformation and rotary inertia. The validity of the present approach is demonstrated by comparing the results with other solutions proposed for plates with uniform and linearly varying thickness. Natural frequencies and mode shapes of Mindlin plates with simply supported and clamped edges are determined for various values of relative thickness ratio and the taper thickness constant. (Author abstract) 19 refs.

**080776 REFINED VIBRATION AND DAMPING ANALYSIS OF MULTILAYERED RECTANGULAR PLATES.** Refined vibration and damping analysis of a general multilayered rectangular plate consisting of an arbitrary number of layers of orthotropic materials has been developed by considering extension, bending, in-plane shear and transverse shear deformations in all the layers and taking into account the rotary and longitudinal translatory inertias along with the transverse inertia of the plate. The solution for a multilayered plate with simply supported edges has been taken in series summation form and resonating frequencies and associated loss factors for plates with alternate elastic and viscoelastic layers have been evaluated by application of the correspondence principle of linear viscoelasticity. Results for three-, five- and seven-layered plates obtained by the present refined analysis are compared with the results obtained by conventional analysis of multilayered plates. (Author abstract) 12 refs.

**080777 THREE-DIMENSIONAL HYBRID-STRESS FINITE ELEMENT FORMULATION FOR FREE VIBRATIONS OF LAMINATED COMPOSITE PLATES.** A three-dimensional eight-node hybrid stress finite element method is developed for the analysis of laminated plates. The hybrid stress model is based on the modified complementary energy principle and takes into account the transverse shear deformation effects. The displacement field is interpolated through shape functions and nodal displacements. All three displacement components are assumed to vary linearly through the thickness of each lamina. All six stresses are included and satisfy the equations of motion. Numerical results for the fundamental frequencies of cross-ply laminates are presented as functions of plate geometry ( $a/h$ ) degree of anisotropy ( $E_L/E_T$ ) and number of plies. They are also compared with numerical values obtained from the elasticity solution, the modified shear deformation theory and the classical lamination theory. (Author abstract) 20 refs.

**080782 MOIRE INTERFEROMETRY FOR VIBRATION ANALYSIS OF PLATES.** Moire interferometry is used to locate nodal regions and measure vibration amplitudes of sinusoidally vibrating square plates. The high sensitivity afforded by this technique makes possible the study of plate vibrations at high frequencies and low amplitudes. The initial pattern is modulated by the zero-order Bessel function representing the vibratory motion. The fringe (or fringes) with best contrast indicate the nodal regions, while the higher order fringes, describing loci of points vibrating with the same amplitude, have decreasing contrast which is improved by spatial filtering. (Author abstract) 6 refs.

Asundi, A. (Univ of Hong Kong, Hong Kong); Cheung, M.T. *Exp Mech* v 27 n 4 Dec 1987 p 338-341.

**080783 RESPONSE OF PLATES TO PULSE EXCITATION.** The ultraspherical polynomial approximation (UPA) technique is presented for the large-amplitude vibrations of thin plates subjected to step function loading, neglecting the longitudinal and rotatory inertia forces. The equations are solved by a one-term solution in spatial coordinates which satisfies the boundary conditions. By proper time transformation of the airy stress function, the time can be eliminated and the stress function can be found. Applying the Ritz-Galerkin method to the deflection equation yields an ordinary nonlinear differential equation in time. An additional transformation function is selected for the displacement variable, to be the solution of the linear system subjected to the same pulse. This reduces the nonlinear differential equation of motion to a form where the ultraspherical polynomial approximation (UPA) technique can be applied to obtain the nonlinear response of plates. The response plots for square and circular plates show that UPA results agree well with Runge-Kutta and linear results. 7 refs.

**080784 FREE VIBRATIONS OF A ROUND ORTHOTROPIC PLATE.** The problem of vibrations of a round orthotropic plate is studied. Expressions are derived for the corrections to the first proper form and the frequency of axisymmetric vibrations. The influence of Poisson's ratio on the natural vibration frequencies is analyzed. (Author abstract) 3 refs.

Bykova, T.I. *Leningrad Univ Mech Bull* n 2 1987 p 52-55.

**080785 VIBRATION AND PARAMETRIC EXCITATION IN ASYMMETRIC CIRCULAR PLATES UNDER MOVING LOADS.** The natural frequencies and modes of transverse vibration of circular plate containing small imperfections are determined through a perturbation method. Incision of equally spaced, equal-size radial slots at the rim of the plate creates asymmetry in some but not all, of the vibration modes, and it causes the repeated natural frequencies of these modes in the symmetric plate to split into two distinct values. These vibration modes are called the split modes, and those associated with the repeated natural frequencies are called the repeated modes. A relationship identifying the split and repeated modes for any configuration of slots is presented. The vibration of a plate containing any number of thin slots cut into it at the rim and with any number of rotating linear springs is analyzed. (Edited author abstract) 13 refs.

**080786 VIBRATIONS OF INITIALLY STRESSED THICK, RECTANGULAR, ORTHOTROPIC PLATES.** Equations of motion for antisymmetric cross-ply laminates in a general state of non-uniform initial stress, where the effects of transverse shear and rotary inertia are included, are derived by the virtual work theorem. The equations are adjusted to a generic expression by using proper transformations. Then, the vibrational behavior of the laminates subjected to a state of uniform tensile or compressive stress plus a uniform bending stress is examined. By considering the transformations, introducing the generalized parameters, and employing a similarity parameter, comprehensive solutions are found to this problem; hence, the curves presented in the text are generic rather than specific. The frequency behavior prior to buckling, undergoes a transition for various mode shape numbers is also investigated. (Author abstract) 17 refs.

**080789 NEW APPROACH FOR THE REPRESENTATION OF A POINT SUPPORT IN THE ANALYSIS OF PLATES.** A new approach for the representation of a point support in the analysis of plates is presented. It is based on the use of a flexibility function, representing the distribution of a fictitious elastic restraint over the boundary, which is such that it has a zero value at the point support location but assumes large values resulting in negligible restraint over the free boundary. The application of this flexibility function approach is demonstrated by considering the free vibrations of rectangular plates with two opposite edges simply supported by mid-point supports on the other two edges which are otherwise free. It is shown that the flexibility function approach as compared to the impulse function approach gives a slightly faster convergence and yields results which are generally very accurate. It is also shown that the flexibility function approach has the scope to simulate practical point support conditions in which the support reaction is spread over a definite band. (Edited author abstract) 18 refs.

**080792 DISTRIBUTED CONTROL OF LAYERED ORTHOTROPIC PLATES WITH DAMPING.** Optimal control of a composite rectangular plate on an electric foundation is studied with the objective of minimizing its dynamic response in a given period of time with the minimum possible expenditure of force. The plate undergoes transient vibrations starting from specified initial displacement and velocity distributions, and the control is exercised by optimally determining the transverse distributed force. The multiple objective of the problem are taken into account by adopting a vector performance criterion comprising quadratic functionals of the deflection, veloc-

ity and distributed force. The sufficiently condition of optimality is derived using control theory results which lead to an analytic solution of the problem. Numerical results are given for simply supported plates made of specially orthotropic layers of boron-fiber-reinforced plastic material. It is demonstrated that the effectiveness of the proposed control depends on the lamination order, foundation modulus, viscous damping, aspect ratio and terminal time as well as on the weight factors attached to various cost functionals. 28 refs.

Adali, S. (Univ of Natal, Durban, S Afr); Sadek, I.S.; Sloss, J.M.; Bruch, J.C. Jr. *Optim Control Appl Methods* v 9 n 1 Jan-Mar 1988 p 1-17.

#### 080793 FINITE PANEL FOR PLATE VIBRATION.

Finite panels are large finite elements which permit plate structures to be analyzed with minimum discretization. Data preparation and computer storage requirements are significantly reduced with finite panels compared with conventional finite elements. A finite panel for the dynamic analysis of plates is presented, extending the existing application which treats the static case. Complete functions are used to represent displacements, with coefficients being chosen by using a modified variational principle. Panel matrices, which are presented in an explicit form, may be used to analyze structures by using standard finite element procedures. The panel has variable degrees of freedom, which enables convergence to be readily assessed. Four examples demonstrate the accuracy of the panel. (Edited author abstract) 14 refs.

**080796 PLATE VIBRATIONS USING B.E.M.** We use the boundary element method (BEM) to solve the problem of natural vibrations of thin plates. The formulation consists of three integral equations, which we reduce to an eigenvalue form by discretizing them using boundary elements, satisfying the boundary conditions of the plate problem. Numerical results of the natural frequencies are presented and compared with previously published results for typical cases of square plates. (Author abstract) 16 refs.

#### 080797 FORCED VIBRATIONS OF INFINITE PLATES.

A number of different analytical expressions are discussed for the forced out-of-plane motion of an infinite plate. The plate is excited on one side with a harmonic pressure at a fairly low frequency. The main result of the discussion is that a region of applicability in the frequency/wavenumber plane is defined for each expression. It is also shown that antisymmetric vibrations (of the bending wave type) are usually of predominant importance for thin plates. Generally, the symmetric vibrations become more important for increasing wavenumbers. However, the symmetric response can be important under coincidence conditions and for the transmission of air-borne sound at grazing incidence, even if the plate is thin compared with the bending wavelength. (Author abstract) 11 refs.

#### 080798 NOTE ON THE ACOUSTIC POWER OUTPUT OF A CIRCULAR PLATE.

The time-average power radiated from individual normal modes of a circular plate clamped at its rim and set in a coplanar rigid baffle is analyzed on the basis of an exact integral representation suitable for frequencies above coincidence. A precise estimate of the radiation at high frequencies is given. (Author abstract) 11 refs.

**080799 STABILITY OF VIBRATIONS OF A PLATE WITH A HYSTERETIC ENERGY DISSIPATION.** In previous studies of vibrations of elastic systems with hysteretic energy dissipation in the material are carried out and expressions for the amplitudes of forced vibrations are given. The stability of stationary vibrations of such systems with concentrated parameters is discussed and it is shown that unstable stationary solutions are possible. In the present article on the example of vibrations of a plate the authors analyze the stability of stationary forced vibrations of systems with distributed parameters as a function of the form of the decrement of vibrations which characterizes energy dissipation.

#### 080801 FREE VIBRATION OF A CANTILEVER ANNULAR SECTOR PLATE WITH CURVED RADIAL EDGES.

An analysis is presented for the free vibration of a cantilever annular sector plate with curved radial edges. For this purpose, the plate is transformed into a regular sector plate with unit outer radius by a transformation of variables. The transverse deflection of the transformed plate is expressed in a power series, the dynamical energies of the plate are evaluated, and the frequency equation is derived by the Ritz method. This method is applied to annular sector plates with symmetrically or unsymmetrically curved radial edges, and the natural frequencies and the mode shapes are calculated

numerically up to higher modes. The eigenvalues obtained here are compared with experimental values of other authors. (Author abstract) 16 refs.

#### 080802 VIBRATIONS OF INITIALLY STRESSED THICK CIRCULAR AND ANNULAR PLATES BASED ON A HIGH-ORDER PLATE THEORY.

The average stress method is used to derive the governing equations for circular and annular plates in a general state of initial stress based on a high-order plate theory. The initial stress is taken to be a combination of an extensional stress plus a pure bending stress in the plane of the plate. These equations are solved by the Galerkin method. Natural frequencies of various boundary conditions are obtained for axisymmetric circular and annular plates. The effects of some parameters on the natural frequencies are studied. The results are compared with those of the Mindlin theory. (Author abstract) 25 refs.

#### 080803 EFFECT OF FIBRE ORIENTATION AND BOUNDARY CONDITIONS ON THE VIBRATION BEHAVIOUR OF ORTHOTROPIC SQUARE PLATES.

Fiber Reinforced Plastics (FRP) are finding increasing applications in aerospace structures due to their high strength to weight and high stiffness to weight ratios. Determination of vibration behavior of structural components made of FRP is necessary for their design. The effect of fiber orientation on the frequencies of thin square orthotropic plates is studied using the Rayleigh-Ritz method for various boundary conditions. The main purpose of the study is to find out in what way boundary conditions influence the frequencies of orthotropic square plates. 5 refs.

#### 080804 FREE VIBRATION OF ANTISYMMETRIC ANGLE-PLY LAMINATED PLATES INCLUDING VARIOUS BOUNDARY CONDITIONS.

An analytical procedure to investigate the free vibration of antisymmetric angle-ply laminated plates is developed. The procedure, based on a generalized Levy-type solution considered in conjunction with the state space concept, enables one to solve exactly the equations governing the laminated anisotropic plate theory as considered by Yang, Norris and Stavsky (YNS). The theory is a generalization of Mindlin's theory for isotropic plates to laminated anisotropic plates and includes shear deformation and rotary inertia effects. The solution is applicable to rectangular plates with two opposite edges simply supported and the remaining ones subjected to a combination of clamped, simply supported and free boundary conditions. The closed form solutions obtained are illustrated numerically in a number of figures and tables revealing the influences of the transverse shear deformation, of the degree of anisotropy, of the geometrical parameters of the plate, of the number of layers, of the ply-angles, and of the character of the boundary conditions. Comparisons with exact and finite element solutions are made. (Edited author abstract) 19 refs.

**080806 ELASTIC-IN-PLANE VIBRATION OF SECTOR PLATES (DERIVATION OF A SERIES SOLUTION).** As is often pointed out, the in-plane vibration in a wedge or a sector plate is one of the most important problems in elastodynamics not to have been solved exactly so far. This problem may be related to the dynamic stress concentration and the scattering of elastic waves by cracks, notches and inclusions. This paper presents an exact series solution for the problem. The series satisfies the governing equations and the boundary conditions given at the two edges of a sector plate term by term. It is shown by use of the solution that the stress singularity at the vertex is the same to that of the corresponding problem in elastostatics. (Author abstract) 3 refs. In Japanese.

**080807 FREE VIBRATIONS OF ORTHOTROPIC PLATES ATTACHED SPRING-MASS SYSTEMS.** An approach is proposed for estimating natural frequency and mode shape of an orthotropic plate which has attached spring-mass systems. The approach consists of three steps: 1) reduction of the governing equation of the plate with attached spring-mass systems to that of a plate with concentrated masses which vary with the vibrating frequency; 2) application of the Receptance method to the reduced governing equation in order to obtain the solution for the governing equation by using the solution of a simple orthotropic plate with neither spring nor mass; and 3) estimation of the natural frequency of the plate with attached spring-mass systems by substituting the above solution into the iterative formula proposed previously by the author. This approach can be applicable to an orthotropic plate with an arbitrary shape and boundary condition. (Edited author abstract) In Japanese.

**080810 VIBRATIONAL BEHAVIOUR OF AN INITIALLY STRESSED ORTHOTROPIC CIRCULAR MINDLIN PLATE.** The virtual work expression for an orthotropic circular thick plate in a general state of non-uniform initial stress, where the effects of transverse shear and rotary inertia are included, is derived. By using a transformation, the natural frequencies of axisymmetric clamped plates and simply supported plates subjected to

initial stresses are investigated in the chosen space, permitting a free vibration study for all composite materials having polar orthotropy. The initial stress is taken to be a combination of a pure bending stress plus an extensional stress in the plane of the plate. Some approximate, but very accurate, standing-wave-type mode shapes are utilized in solving the essentially double eigenvalue problem by a Ritz-Galerkin method to determine the effects of various parameters on the natural frequencies. (Author abstract) 24 refs.

**080811 ANALYSIS OF FREE FLEXURAL VIBRATION OF RECTANGULAR PLATES BY THE FINITE DIFFERENCE TRANSFER MATRIX METHOD.** This paper is concerned with the analysis of free flexural vibration of rectangular plates by the finite difference transfer matrix method. In this method, the algebraic computations are conducted by the transfer matrices which are formulated with the use of the ordinary finite difference equations for the differential equation of plate vibration. The proposed method is efficient to reduce the size of the coefficient matrix of simultaneous equation in the ordinary finite difference method and finite element method. Some numerical results are also presented to prove that the proposed method has the wide applicability and possibility of future development of structural analysis. (Author abstract) In Japanese. 42 refs.

**080812 FREE VIBRATIONS OF A RECTANGULAR PLATE-CAVITY SYSTEM.** This paper presents a method for computing the natural frequencies and mode shapes of a rectangular plate backed by a closed rectangular cavity. The plate motion is represented by a number of admissible functions consisting of in vacuo normal modes for simply supported plates, and of beam functions for fully clamped plates. The acoustic motion is described analytically in terms of such functions. This allows the vibration of the entire system to be adequately treated in terms of a small number of plate modes. The free vibration solution for the coupled system is obtained either directly by solving the plate equation of motion or by formulating the mass and stiffness matrices of each subsystem numerically. For practical application, a simplified equation is developed to calculate the fundamental natural frequency. (Author abstract) 7 refs.

**080815 NATURAL FREQUENCIES OF MINDLIN PLATES OF BILINEARLY VARYING THICKNESS.** The objective of the work reported in this letter is to use the method presented by G. Aksu and S.A. Al-Kaabi to examine the dynamic behaviour of rectangular plates with bilinearly varying thickness, including both transverse shear and rotary inertia. Two types of bilinear variation which are symmetric with respect to mid-axis are considered. The natural frequencies and mode shapes have been computed for various values of the thickness parameter and taper thickness ratio. New findings are presented for various boundary conditions, and the results are compared with existing solutions based on the thin plate theory. 6 refs.

**080820 ANALYTICAL SOLUTION FOR THE POWER EXCHANGE BETWEEN STRONGLY COUPLED PLATES UNDER RANDOM EXCITATION: A TEST OF STATISTICAL ENERGY ANALYSIS CONCEPTS.** The response of the structural components of a complex structure, subjected to random loads, is often estimated by approximate methods based on the concepts of Statistical Energy Analysis (SEA). To examine the fundamental SEA postulates and assumptions, the problem of two coupled plates is rigorously formulated and solved in terms of usual SEA variables. For randomly distributed loads, analytical results are presented for the power flow and plate vibrational energies. The formulation allows the extraction of "apparent" quantities that correspond to the coupling loss factor and modal density ratio of statistical energy analysis. It is demonstrated that this model can yield an understanding of the implications of basic SEA assumptions. Results for simply supported plates clearly show the effects of internal damping and frequency on the coupling parameters. (Author abstract). 15 Refs.

**080821 POWER RADIATED BY AN INFINITE PLATE SUBJECT TO FLUID LOADING AND LINE DRIVE.** Fluid-loading effects on the acoustic and vibration response of a thin elastic plate can be specified by a phase Mach number or frequency parameter  $M = k_0/k_p$  and an intrinsic fluid-loading parameter  $\epsilon$ . In this paper asymptotic expressions are given for the acoustic power radiated by a thin plate under line force drive, covering the entire frequency range  $0 < M < \infty$  in the limit  $\epsilon \rightarrow 0$ . These expressions reflect the balance of physical mechanisms in each of four principal frequency ranges and, for the case of steel plates with water loading, are shown to agree extremely well with previously published numerical evaluations of the acoustic power. (Author abstract). 18 Refs.

**080822 NONLINEAR FORCED VIBRATION OF ORTHOTROPIC THIN A RECTANGULAR PLATES.** This study deals with the large amplitude forced vibrations of specially orthotropic thin rectangular plates. Geometric nonlinearity is included in accordance with von Karman type large deflection plate theory. The transverse displacement is assumed to be harmonic at the same frequency as that of the uniformly distributed harmonic force. The displacements are expanded space-wise in terms of polynomial basis functions which satisfy the boundary conditions. Time is eliminated by averaging over the time-period of the harmonic force. The orthogonal point collocation method is used to obtain the discretized equations. (Edited author abstract). 11 Refs.

**080823 DETERMINATION OF ELASTIC CONSTANTS OF ORTHOTROPIC PLATES BY A MODAL ANALYSIS RAYLEIGH-RITZ TECHNIQUE.** The first part of this paper describes a computer programme in which equations derived by the Rayleigh-Ritz technique are used to model the vibrations of rectangular orthotropic plates. The characteristic functions of vibrating beams were used as the assumed functions for plates with boundary conditions consisting of clamped and free edges. Natural frequencies and mode shapes from the programme were verified by finite element analysis and modal analysis for square aluminium and graphite/epoxy plates. The plate vibration model was then

incorporated into a second computer programme which was designed to use the measured natural frequencies of orthotropic plates to determine the four apparent elastic constants. Natural frequencies measured by an impulse technique were used to determine two Young's moduli, the in-plane shear modulus, and a Poisson ratio for each plate. (Author abstract). 36 Refs.

**080824 VIBRATION OF A BIMODULUS THICK PLATE ACCORDING TO A HIGHER-ORDER SHEAR DEFORMATION THEORY.** Equations of motion of a simply supported rectangular bimodulus thick plate in which the higher-order-shear deformation terms are included are derived. The governing equations using the average stress method are solved in exact form. The natural frequencies are compared with the previous results obtained for ordinary thick plates, and with the neutral surface locations and natural frequencies of bimodular plates. From those comparisons, the effects of the higher-order shear deformation terms on the neutral surface locations and the natural frequencies can be observed. Also, the percentage error sense improvement by higher-order deformation terms can be reduced from 1.4 to 0.09 percent. (Author abstract). 25 Refs.

**080825 NATURAL RESPONSE OF BIAXIALLY LOADED PLATES.** Although the characteristic equation for the natural vibration of a biaxially loaded plate is well-known, there appears to be no detailed study of this important problem. This is surprising since analytical derivations of those modal shapes of main practical interest are relatively easy to obtain, thus enabling the corresponding frequencies to be derived. In the present paper it is shown how the problem can be tackled for all four combinations of biaxially applied stress states; in addition, a full parametric study of the first four modes for the biaxial compression case is carried out. (Author abstract). 8 Refs.

Pavlovic, Milija N. (Imperial Coll, London, Engl); Baker, Graham. *Int J Struct* v 8 n 1 Jan-Jun 1988 p 15-39.

**080826 VIBRATION OF SHEAR-DEFORMABLE LAMINATED PLATE STRUCTURES BY THE FINITE STRIP METHOD.** Free vibration of prismatic plate structures of laminated composite material and having diaphragm end supports is considered using the finite strip method. Description is given of the development of stiffness and mass matrices for both out-of-plane and in-plane deformation of a family of strip models. The former deformation is based on first-order shear deformation plate theory, rather than classical plate theory. Frequency calculations are made using full sets of structure equations and using reduced sets obtained from an economization procedure. Presented results demonstrate the good convergence characteristics of the finite strip approach and reveal the relative efficiency of particular economization schemes. Comparison made with results based on the use of classical plate theory in deriving out-of-plane strip properties shows that the effects of through-thickness shear and rotary inertia on a natural frequency are heavily dependent upon the nature of the associated mode shape. (Author abstract) 31 refs.

## Viscoelasticity

**080827 LINEAR VOLTERRA INTEGRODIFFERENTIAL EQUATION FOR VISCOELASTIC RODS AND PLATES.** It is proved that the resolvent kernel of a certain Volterra integrodifferential equation in Hilbert space is absolutely integrable on  $(0, \infty)$ . Weaker assump-

tions on the convolution kernel appearing in the integral term are used than in existing results. The equation arises in the linear theory of isotropic viscoelastic rods and plates. (Author abstract) 12 refs.

Noren, Richard D. (Old Dominion Univ, Norfolk, VA, USA). *Q Appl Math* v 45 n 3 Oct 1987 p 503-514.

**080828 PLANE PROBLEMS OF LINEAR VISCOELASTICITY FOR PLATES WITH CURVILINEAR ANISOTROPY.** The investigation of complex problems in the mechanics of materials with curvilinear anisotropy entails considerable difficulties. These difficulties stem primarily from the fact that it is not possible to directly employ methods based on the use of the theory of analytic functions. For such problems (in relation to elastic materials), an asymptotic method has been proposed that makes it possible to separate the stress-strain state of the plate into two components, which can be determined through successive solution of boundary value problems of potential theory. In this paper, the ideas of the asymptotic method in question are generalized to the case of an orthotropic viscoelastic medium. We consider materials that display primarily shear creep (in many cases, such properties are displayed, e.g., by glass-reinforced plastics). (Edited author abstract) 6 refs.

## Wave Effects

**080829 RAYLEIGH-LAMB WAVES IN AN ELASTIC PLATE WITH VOIDS.** Rayleigh-Lamb waves in a homogeneous and isotropic linear elastic plate containing a distribution of vacuuous pores (voids) are studied. Assuming that the plate is of uniform thickness and that its faces are stress-free, it is found that the waves move, in general, in two uncoupled families, of which one is symmetrical with respect to the midplane of the plate and the other antisymmetrical; each of these families is affected by the presence of voids. If the plate is thin and the frequency is small, the voids influence only the symmetric waves and, because of this influence, the waves propagate slower than their classical counterparts. If the plate thickness and the frequency are large, each of the two families degenerates into two uncoupled waves; one of these is a classical Rayleigh wave and the other is a new wave not encountered in the classical theory. (Author abstract) 14 refs.

Chandrasekharaiah, D.S. (Bangalore Univ, Bangalore, India). *J Appl Mech Trans ASME* v 54 n 3 Sep 1987 p 509-512.

**080830 UNSTEADY LAMINAR BOUNDARY LAYERS SUBJECT OF STANDING WAVE OR TRAVELLING WAVE FREESTREAM FLUCTUATIONS.** Calculations of laminar boundary layer development on a flat plate under the influence of an unsteady freestream velocity have been conducted using the numerical procedure of Cebeci and Carr which was modified to accommodate both standing wave and travelling wave freestream conditions. Results for both types of freestream velocity fluctuations over a range of values of the reduced frequency and freestream convection velocity are reported. For the standing wave freestream conditions the velocity near the wall, and therefore the wall shear stress, exhibits a phase lead with respect to the freestream velocity, reaching a maximum value of  $45^\circ$  at high values of the reduced frequency. Under travelling wave freestream conditions the velocity near the wall shows a phase lag with respect to the freestream velocity. (Edited author abstract). 13 Refs.

## Chemical Analysis

**080833 EXTRACTION-FLUOROMETRIC DETERMINATION OF PLATINUM(IV) WITH RHODAMINE 6G.** Attempts to use rhodamine dyes for the extraction-fluorometric determination of platinum proved unsuccessful since rhodamine 6G in acid bromide and chloride solutions forms water-insoluble and benzene-unextractable ion associates with platinum(IV). This paper reports a comprehensive study of the fluorescent reaction of platinum(IV) with rhodamine 6G and develops an extraction-fluorometric determination of microgram amounts of platinum. 7 refs.

## Chemical Reactions

**080834 STUDY ON THE COLOUR REACTION OF PLATINUM WITH 4,4'-Bis-(DIMETHYLAMINO) THIOBENZOPHENONE.** A highly sensitive colour reaction of platinum with 4,4'-bis-(dimethylamino) thio-benzophenone (Thio-Michler's ketone, TMK) has been investigated. Maximum absorbance is attained after 15min. in boiling water in the presence of certain amounts of Triton X-100 and ascorbic acid. The colour reaction can be highly selective when EDTA and  $NH_4F$  are used as masking agents. This reaction can be applied to the spectrophotometric determination of microamounts of platinum in pure nickel or pure silver. (Edited author

**080835 EFFECT OF SURFACE-ACTIVE MATERIALS ON THE REACTION OF PLATINUM(II) WITH 4-(2-PYRIDYLAZO)RESORCINOL.** The effect of cationic and anionic surface-active materials (SAM) on the reaction of Pt(II) with 4-(2-pyridylazo)resorcinol (PAR) was investigated. It was established that addition of SAM to the platinum-PAR system is very effective, since they increase not only the sensitivity of this reaction, but also shorten the time of reaching a complexing equilibrium. (Author abstract) 8 refs.

**Chemical Vapor Deposition** See Also ELECTRIC CONTACTS, OHMIC—Fabrication.

**080836 GAS PHASE VERSUS SURFACE CONTRIBUTIONS TO PHOTOLYTIC LASER CHEMICAL VAPOR DEPOSITION RATES.** The rate of cw photolytic laser chemical vapor deposition (LCVD) of platinum is measured for approximately 350 nm as a function of the light intensity and the metalorganic vapor pressure. The growth of the metal films is studied in situ and in real time by monitoring their optical transmission. At low intensities the transmitted light decreases monotonically with time, and the LCVD process is photolytic with its rate limiting step in the surface adlayer. At higher intensities we observe two distinct time domains: relatively slow initial photolytic deposition with its rate limiting step in the gas phase, which is followed by much faster pyrolytic LCVD. An improved method for distinguishing between adlayer and gas-phase limiting processes is demonstrated. These observations are confirmed by studying the photolytic deposition rates while varying the thickness of the adlayer. (Author abstract) 12 refs.

## Chlorination

**080837 REACTION OF PLATINUM WITH CHLORINE IN A POTASSIUM CHLORIDE MELT.** In the paper results are presented of a study of the chemical forms in which platinum is found in the products of its chlorination in a KCl melt, and also data on the kinetics of this reaction. The temperature range studied was 800-1000°C. The kinetics of the process were studied by a gravimetric method. The results of chemical analysis indicated that the change in weight of the reaction mixture was proportional to the change in the concentration of platinum ions in the melt. 13 refs.

## Economics

**080839 PLATINUM: THE VIEW FROM SOUTH AFRICA.** This article discusses the properties of platinum and its applications as a high technology metal. World reserves of this strategic and precious metal are confined mostly to South Africa and to a lesser extent, the Soviet Union. An analysis is given of past trends in world platinum output. The time-path is computed for the world platinum output rate covering a period of more than 350 years. This is based on the postulate that the industrial conversion of a virgin resource progresses according to a sigmoid curve. The price dynamics are examined and forecast. 28 refs.

Feichtinger, F. (Isacor, Vanderbijlpark, S Afr); Lammer, A.; Riess, M. *Min Eng (Littleton Colo)* v 40 n 2 Feb 1988 p 91-95.

**080840 PLATINUM EXPERTS PREDICT DEMAND COULD REACH 93 t (3 MILLION oz) DESPITE PRICE FLUCTUATIONS.** For the third successive year it appears that demand for platinum will exceed supplies of newly-mined metal. Based on data available at the end of August 1987, Johnson Matthey estimates that western world demand for platinum could exceed 93t (3 million oz) for the first time in 1987. Given a likely increase in demand of 4.3t to around 94t (140,000 oz to around 3.02 million oz), up by about 5% over 1986, there would be a 1.8- to 2.2-t (60,000- to 70,000-oz) shortfall in 1987 supply.

## Electrolytic Analysis

**080841 EXTRACTION-VOLTAMMETRIC DETERMINATION OF PLATINUM AND OSMIUM IN SULFIDE ORES BY CATALYTIC HYDROGEN CURRENTS.** Wider practical uses of platinum metals necessitate improvements in methods for analytically monitoring their products and raw materials. Difficulties arise because of their close chemical and analytical properties as well as their low contents. Catalytic hydrogen evolution currents (CHEC) in solutions of platinum-metal complexes with organic ligands permits voltammetry to be competitive with physical methods in sensitivity. Solid-phase extraction with low-melting extractants can raise selectivity and achieve considerable preconcentration. This paper shows the possibility of determining osmium and platinum in the presence of other platinum and noble metals. The reagent was sodium 2-methyl-8-mercaptoquinoline which yielded large differences in potential maxima. 6 refs.

**Electroplating** See ELECTRODES—Materials.

## Leaching

**080842 LEACHING KINETICS OF PLATINUM AND PALLADIUM FROM SPENT AUTOMOTIVE CATALYSTS.** Empirical rate expressions for both platinum and palladium were obtained from mass balances and concentration-time data in a packed bed reactor using different (HCl):(HNO<sub>3</sub>) leaching solution concentration ratios. The spent catalysts used in this study (—60+70 mesh to —120+140 mesh) were analyzed to be 3791 ppm

platinum and 1306 ppm palladium. High initial rates for both platinum and palladium were obtained for the early stages of leaching and were followed by rapid decay up to about 110 minutes and 50 minutes, respectively. Typical concentrations in the leached solution were about 40 ppm Pt and 20 ppm Pd after about 5 hours for the experimental conditions used. (Edited author abstract) 33 refs.

Tyson, David R. (Iowa State Univ, Ames, IA, USA); Bautista, Renato G. *Sep Sci Technol* v 22 n 2-3 Feb-Mar 1987, Fourth Symp on Sep Sci and Tec for Energy Appl, Knoxville, TN, USA, Oct 20-24 1985 p 1149-1167.

**080843 REFLECTANCE AND RAMAN SPECTRA OF MIXED CRYSTALS OF QUASI-ONE-DIMENSIONAL MIXED-VALENCE PLATINUM COMPLEXES**  $[Pt^{3+}P(en)_2][Pt^{3+}P(Cl_{1-x}Br_x)_2(en)_2](ClO_4)_4$  ( $0 \leq x \leq 1$ ,  $0 < p \leq 1$ ). Mixed crystals of halogen-bridged mixed-valence platinum complexes  $[Pt^{3+}P(en)_2][Pt^{2+p}(Cl_{1-x}Br_x)_2(en)_2](ClO_4)_4$  ( $0 \leq x \leq 1$ ,  $0 < p \leq 1$ ) are studied by reflectance and Raman scattering measurements. Quasi-one-dimensional charge transfer excitons in these mixed crystals are of the 'amalgamation' type with large optical bowing. The energies of the phonons related to the Peierls distortion shift with composition  $x$  and their resonant Raman intensities diminish rapidly by the introduction of different halogens. These effects are discussed in terms of modulated charge density waves in one-dimensional mixed crystals. (Author abstract) 18 refs.

**Production** See PLATINUM METALS—South Africa.

## Recovery

**080845 PHYSICO-CHEMICAL BASIS OF PRODUCTION OF A HIGH-STRENGTH ABSORBENT MASS FOR RECOVERY OF PLATINUM METALS.** The purpose of this work was study of the influence of the main technological parameters (initial composition of the mixture, ratio of the amount of water to the total dry components, molding pressure) on the compressive strength of heat-treated samples of absorbent masses for recovery of platinum metals. It was shown that the mechanical strength of the absorbent mass depends significantly on its content of calcium aluminate of the composition  $12CaO \cdot 7Al_2O_3$ . Experimental production trials of the absorbent mass studied demonstrated its high selectivity for platinum and good resistance to mechanical and chemical influences. 10 refs.

## Research

**080846 SYNTHESIS AND STRUCTURE OF  $[Pt_2(\eta^5-C_5Me_5)_2(CO)_2]$ , A CONVENIENT PRECURSOR TO PENTAMETHYLCYCLOPENTADIENYL CHEMIS-**

**TRY OF PLATINUM.** The author describes a new high-yield synthetic method to this important starting material. A single-crystal X-ray structure determination of 1 revealed it to contain two  $Pt(\eta^5-C_5Me_5)(CO)$  subunits, the two adjacent terminal carbonyl groups being orientated at approximately  $105^\circ$  to each other. The carbonyl groups bend over (average angle  $79.7^\circ$ ) the platinum-platinum bond whose length of 263.6 pm is at the long end of the range reported for platinum(I) dimers, possibly as a result of steric congestion between the two pentamethylcyclopentadienyl groups. 15 refs.

## Separation

**080847 ISOLATION AND SEPARATION OF PLATINUM METALS BY EXTRACTION CHROMATOGRAPHY.** In this paper we propose a new approach to isolation and separation of platinum metals by extraction chromatography, based on the use of extraction systems consisting of mixed hydrochloric-sulfuric acid solutions with tributyl phosphate. It is found that separation of platinum, palladium and iridium from rhodium is accompanied by, on the average, fivefold concentrations of the three former elements in a solution convenient for subsequent operations. In the fractions of these elements rhodium could not be detected in amounts down to  $10^{-2}\%$  of its content in the original mixture. 10 refs.

**080849 STUDY BY XENON NMR OF PLATINUM PARTICLES SUPPORTED ON ALUMINA.** The surface of platinum supported on alumina was probed by  $^{129}Xe$  NMR. In particular, the amount of adsorbed hydrogen and oxygen as well as the reaction of adsorbed hydrogen with dioxygen could be followed by NMR spectra. The results show that metals supported on nonmicroporous materials can be probed by  $Xe$  NMR as previously demonstrated for metals in zeolites. The  $Xe$  NMR method of surface probing seems to be broadly applicable to many adsorbents used in surface chemistry and heterogeneous catalysis. (Edited author abstract). 15 refs.

**080851 ULTRATHIN PLATINUM FILMS ON MICA AND THE MEASUREMENT OF FORCES AT THE PLATINUM/WATER INTERFACE.** The chemical stoichiometry and structure of 2-10-nm-thick Pt films deposited on molecularly smooth mica have been characterized by Auger electron spectroscopy, transmission electron microscopy, electron diffraction, and direct-phase-detection microscopic interferometry. These analyses are correlated with electrical, optical, and electrochemical properties of the films with regard to their use in surface forces microbalance techniques. Large-area ( $1\text{ cm}^2$ ), 4-nm-thick polycrystalline films are sufficiently conductive and transparent to allow measurement of forces between metallic phases. Preliminary measurements of electrostatic forces between two Pt films separated by a thin layer of water are presented. (Edited author abstract) 37 refs.

## PLATINUM COBALT ALLOYS

### Electrodeposition

**080854 ELECTROLYTISCH ABGESCHIEDENE PLATIN-KOBALT-LEGIERUNGSSCHICHTEN.** [Electrodeposited Platinum-Cobalt Alloy Coatings. Mechanical and Magnetic Properties]. The electrodeposition of

Pt-Co alloys from solutions based on  $\text{Pt}(\text{NO}_2)_2(\text{NH}_3)_2$  and  $\text{CoSO}_4$  has been examined in a wide range of deposition conditions. In addition to composition, internal stresses, hardness and crystallographic properties of the coatings, their magnetic properties in the deposition state were determined. (Edited author abstract) In German. 7 refs.

Baumgaertner, M.E.; Raub, Ch.J.; Cavallotti, P.; Turrilli, G. *Metalloberflaechen* v 41 n 11 Nov 1987 p 559-563.

## PLATINUM COMPOUNDS See Also OXYGEN—Reduction; POTASSIUM COMPOUNDS.

**080855 ON THE GROWTH OF  $\text{PtCl}_3$  CRYSTALS FROM THE VAPOUR PHASE.** Crystals of  $\text{PtCl}_3$  are obtained from the vapor phase in closed fused silica ampoules at temperatures near 785 K and at a chlorine pressure of about 26 atm. The thermodynamic parameters characterizing the single-phase field of solid  $\text{PtCl}_3$  are determined. The growth of the crystals results from vapor transport which is a combination of a sublimation and two dissociative reactions. The complex transport is investigated using the solubility theory of Schaefer. The theory reveals an increase in the transport rate with increasing chlorine pressure when the source is heated to the temperature which separates the fields of solid  $\text{PtCl}_2$  and  $\text{PtCl}_3$ . (Author abstract) 16 refs.

Schoenherr, E. (Max-Planck-Institut fuer Festkoerperforschung, Stuttgart, West Ger); Wojnowski, M.; Rabenau, A.; Lacher, S. *J Less Common Met* v 137 Feb 1 1988 p 277-286.

## Adsorption

**080856 ADSORPTION PROPERTIES OF PLATINUM OXIDES.** The adsorption of organic compounds having different ionization potentials (I) was studied on powdered oxides of platinum having different valences. The values of I at which chemical bonding arises between the adsorbate and adsorbent were found for each oxide. The data obtained were compared with results of adsorption studies performed at platinum at high anodic potentials. (Author abstract) 12 refs.

Nechaev, E.A. (F.E. Dzerzhinskii Chemical Engineering Inst, Dnepropetrovsk, USSR); Silina, T.F. *Sov Electrochem* v 22 n 11 Nov 1986 p 1453-1457.

## Electric Properties

**080857 ELECTRICAL PROPERTIES OF QUASI-ONE-DIMENSIONAL SEMICONDUCTOR HALOGEN-BRIDGED PLATINUM COMPLEXES.** The dark current and photocurrent of  $[\text{Pt}(\text{en})_2][\text{Pt}(\text{en})_2(\text{I}_{1-y}\text{X}_y)_2](\text{ClO}_4)_4$  ( $0 \leq y \leq 0.05$ ,  $\text{X} = \text{Cl}$  and  $\text{Br}$ ,  $\text{en} = \text{ethylenediamine}$ ), have been measured as a function of temperature and light intensity. The conductivity shows an activation-type conduction, but the carriers responsible for the conduction do not originate from the minor halogen ions. The activation energy and the photon energy where the photoconduction starts increase as the contents of  $\text{Cl}$  or  $\text{Br}$  increase. The binding energy of the charge transfer exciton is estimated to be  $0.3 \pm 0.05$  eV. (Author abstract) 10 refs.

Haruki, M. (Yokohama Natl Univ, Yokohama, Jpn); Tanaka, M.; Kurita, S. *Synth Met* v 21 n 3 Oct 1987, Proc of the Conf on Electron Processes in Conduct Polym, Part III, Vadstena, Swed, Aug 18-20 1986 p 373-378.

## Hydrogenation

**080858 ISOTOPIC EXCHANGE REACTIONS OCCURRING IN THE HYDROGENATION OF (1,5-CYCLOOCTADIENE)DIALKYLPLATINUM(II) COMPLEXES OVER PLATINUM BLACK.** The authors examine the relative rates with which deuterium is transferred from deuterated alkyls,  $\text{R}^{\text{D}}$ , into the cyclooctane product (during hydrogenation with  $\text{H}_2$ ) as a function of the structure and position of isotopic substitution of the alkyl moiety. Based on experimental evidence, it is evident that the range of isotopomers of cyclopentane

is broader than the range of isotopomers of propane from reduction of either their parent organoplatinum complexes or alkenes. 33 refs.

Miller, Timothy M. (Harvard Univ, Cambridge, MA, USA); Whitesides, George M. *J Am Chem Soc* v 110 n 10 May 11 1988 p 3164-3170.

## Ion Implantation

**080859 INFLUENCE OF ARGON IMPLANTATION ON THE FORMATION OF PLATINUM SILICIDES.** This study used transmission electron microscopy and electron diffraction techniques to investigate structural and phase composition features of platinum silicides formed by rapid thermal annealing of argon implanted and unimplanted platinum films on monocrystalline silicon. The structures used in the experiment were 40 nm platinum films deposited onto (111) silicon substrates. Implanted and unimplanted samples were isothermally annealed in the thermal balance regime with induced temperatures of 300 to 800°C for 10 to 30 s. The stimulating role of ion implantation with small doses is probably connected with recoil atom mixing at the platinum-silicon interface. 5 refs.

Borisenko, V.E. (Minsk Radioengineering Inst, Minsk, USSR); Zarovskii, D.I.; Tokarev, V.V. *Phys Status Solidi A* v 107 n 1 May 1988 PK33-K35.

## Optical Properties

**080860 MAGNETIC-FIELD AND TEMPERATURE EFFECTS ON THE OPTICAL PROPERTIES OF DICIANO-2,2-BIPYRIDYL-PLATINUM(II) SINGLE CRYSTALS.** Studies of the polarized emission of  $[\text{Pt}(\text{CN})_2(\text{bipy})]$  single crystals as function of temperature ( $1.9 \text{ K} \leq T \leq 295 \text{ K}$ ) and homogeneous magnetic fields ( $0 \leq H \leq 6 \text{ T}$ ), and the temperature dependence of the polarized absorption spectrum are reported. Raising the temperature from 1.9 to 7 K or increasing the magnetic field from 0 to 1 T results in a blue shift of approximately  $175 \text{ cm}^{-1}$  in the ELA polarized emission (E: electric field vector, a: crystallographic axis). Between 1.9 and 295 K (at  $H=0$ ) and between 0 and 6 T (at  $T=1.9 \text{ K}$ ), the emission lifetime decreases by factors of approximately  $10^3$  and approximately  $10^2$ , respectively. The results are explained within the  $C_{2v}$  symmetry of the single complex assuming a coupling between neighboring central ions. (Author abstract) 14 refs.

Biedermann, J. (Univ Regensburg, Regensburg, West Ger); Wallfahrer, M.; Gliemann, G. *J Lumin* v 37 n 6 Oct 1987 p 323-329.

## Oxidation

**080861 OXIDATION OF  $\text{PtSi}$ ,  $\text{Pt}_2\text{Si}$  AND POLYCRYSTALLINE SILICON IN ULTRAHIGH VACUUM RESIDUAL GAS.** The effect of electron bombardment and the filament current of the ion gun on the oxidation of polycrystalline silicon (poly-Si),  $\text{PtSi}$  and  $\text{Pt}_2\text{Si}$  was studied by means of Auger electron spectroscopy. The oxidation was carried out in the residual gas ( $5 \times 10^{-8} \text{ Pa}$ ), i.e. without any oxygen introduced into the ultrahigh vacuum system. The electron bombardment was accomplished by irradiating the surfaces with 3 keV electrons at a beam current of 20  $\mu\text{A}$ . It was found that the silicon in  $\text{PtSi}$  and  $\text{Pt}_2\text{Si}$  oxidizes under the influence of electron bombardment or when the filament of the ion gun is heated. Under these conditions only the initial stage of silicon oxidation could be detected in poly-Si. (Author abstract) 11 refs.

Swart, H.C. (Univ of the Orange Free State, Bloemfontein, S Afr); Louw, C.W.; Berning, G.L.P. *Thin Solid Films* v 158 n 1 Mar 1988 p 61-67.

## Physical Properties

**080862 PHYSICAL PROPERTIES OF METAL CLUSTER COMPOUNDS. III: NMR STUDY OF PLATINUM CARBONYL CLUSTERS.** The Pt NMR line shapes for  $[\text{Pt}_3(\text{CO})_4\text{H}_2]$ ,  $[\text{N}(\text{PPh}_3)_2]_2$  and  $[\text{Pt}_{26}$

$(\text{CO})_{32}\text{H}_2]$   $[\text{PPh}_4]_2$  resemble those found in free Pt-particles of comparable size. Our analysis does not allow a discrimination between Knight or chemical shift. It is suggested that the Pt-relaxation rate, which normally gives another tool to check the mechanism of the shift, is determined by the presence of paramagnetic electronic spins as seen both in ESR and in the magnetic susceptibility. (Author abstract) 25 refs.

Pronk, B.J. (Rijksuniversiteit Leiden, Leiden, Neth); Brom, H.B.; Ceriotti, A.; Longoni, G. *Solid State Commun* v 64 n 1 Oct 1987 p 7-10.

Recovery See ION EXCHANGE RESINS—Industrial Applications.

## Reduction

**080863 ELECTROREDUCTION OF  $\text{PtCl}_4^{2-}$  IONS IN DIHYDRIC ALCOHOLS.** The authors studied  $\text{PtCl}_4^{2-}$  ion discharge in ethylene glycol (EG) as well as in 1,2- and 1,3-propanediol (propylene glycol, PG) at the dropping mercury electrode. All salts and solvents used in the work were subjected to special purification. The 1,2- and 1,3-PG after prolonged shaking with lithium hydroxide were twice distilled and stored under inert gas. Applicability of slow discharge theory to the electroreduction of  $\text{PtCl}_4^{2-}$  ions was checked quantitatively by determination of the transfer coefficient  $\alpha$  and of charge  $z_0$ . The experimental currents were corrected for concentration polarization. It is seen when investigating the electroreduction of  $\text{PtCl}_4^{2-}$  in EG and 1,2-PG that the experimental data can be explained by a slow electrochemical discharge step. Furthermore the  $\text{PtCl}_4^{2-}$  ions behave similarly in EG and 1,2-PG. 6 refs.

Shavgulidze, V.V. (Acad. Sciences of the Georgian SSR, Tbilisi, USSR); Ketiladze, D.D. *Sov Electrochem* v 22 n 9 Sep 1986 p 1188-1190.

**080864 MECHANISM OF CATHODIC  $\text{PtCl}_6^{2-}$  REDUCTION TO PLATINUM CLUSTERS ON ELECTRODES COATED WITH POLYVINYL-PYRIDINIUM FILMS.** The electrochemical reduction of  $\text{PtCl}_6^{2-}/\text{HCl}$  to  $\text{Pt}^0$  is investigated on electrodes coated with anion exchange polymer films. The first step is the cathodic reduction to  $\text{PtCl}_4^{2-}$ . Three possible routes for the reaction  $\text{PtCl}_4^{2-}$  to  $\text{Pt}^0$  are discussed: (i) a second electrochemical step; (ii)  $\text{PtCl}_4^{2-}$  disproportionation; (iii) reduction by cathodically produced  $\text{H}_2$ . It is demonstrated that route (i) is normally dominant. The  $\text{Pt}^0$  produced has a large surface area. Individual microparticles ('clusters') can be conveniently formed. As expected from the electrochemical mechanism the  $\text{Pt}^0$  produced is located at the electrode-coating interface. (Author abstract) 16 refs.

Kowal, Andrzej (Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, West Ger); Doblhofer, Karl; Krause, Siegfried; Weinberg, Gisela. *J Appl Electrochem* v 17 n 6 Nov 1987 p 1246-1253.

## Synthesis

**080865  $\beta$ - $\text{PtO}_2$ : HIGH PRESSURE SYNTHESIS OF SINGLE CRYSTALS AND STRUCTURE REFINEMENT.** Single crystals of  $\beta$ - $\text{PtO}_2$  have been grown from  $\text{Pt-KClO}_3$ -mixtures at 40 kbar, 1500°C in a modified Belt-type apparatus using Pt capsules. The crystals are orthorhombic, space group  $\text{Pnmm}$ , with  $a = 4.4839(3)$  Angstrom,  $b = 4.5385(6)$  Angstrom,  $c = 3.1360(6)$  Angstrom and  $Z = 2$ . Single crystal X-ray data confirmed the structure to be  $\text{CaCl}_2$ -type, a distorted variant of the rutile structure. The Pt-O distances are  $2 \times 1.989(4)$  and  $4 \times 2.003(4)$  Angstrom, the shortest oxygen-oxygen distance is  $2.494(5)$  Angstrom. A discussion of some geometrical features is presented. (Author abstract) 22 refs.

## Thermodynamic Properties

**080866 STANDARD ENTHALPIES OF FORMATION OF PTI, PTZr, AND PTHf.** The standard enthalpies of formation of the intermetallic compounds PtTi, PtZr, and PTHf have been determined by high temperature mixing calorimetry in a new calorimeter operated at (1473  $\pm$  2) K. The following values of  $\Delta H_f^\circ$  are reported. PtTi:  $-159.3 \pm 12.9$  kJ mol $^{-1}$ ; PtZr:  $-191.9 \pm 12.4$  kJ mol $^{-1}$ ; PTHf:  $-227.3 \pm 13.2$  kJ mol $^{-1}$ . These results are compared with recent experimental values obtained by high temperature direct combination calorimetry, with predicted values and with our own recently published data for the equiatomic alloys of Ti, Zr, and Hf with Pd, Rh, and Ru. The enthalpies of formation of the Pt compounds are significantly more exothermic than the corresponding Pd, Rh, and Ru compounds. (Author abstract) 24 Refs.

## PLATINUM MANGANESE IRON ALLOYS

## Magnetic Properties

**080868 MAGNETIC STATE OF QUASIBINARY SOLID SOLUTIONS  $Pt_3M_{x\%}Fe_{1-x}$  NEAR THE CRITICAL CONCENTRATION.** The authors measured the magnetization of two specimens with x=0.3 and 0.4, taken from the near vicinity of the critical concentration in the range 4.2  $\leq$  T  $\leq$  300 K. The  $\sigma(T)$  curves measured at H=1.5 tesla have a maximum which practically coincides with  $T_N$  found from neutron diffraction data. Cooling specimens in a magnetic field H=1.5 tesla from T=300 K  $>$   $T_N$  to T=4.2; 20.4 and 79 K  $<$   $T_N$  has no appreciable effect on  $\sigma(T)$  for the alloy with x=0.3 but raises the magnetization of the alloy with x=0.4. Some of the properties of the alloys with x  $>$   $x_c$  and for the alloy with x=0.4 in particular at T  $<$   $T_N$  and H < 8 tesla are typical of the spin glass state. 6 refs.

**080869 PLATINUM-GROUP MINERALS FROM HOCHGROSSEN ULTRAMAFIC MASSIF, STYRIA: FIRST REPORTED OCCURRENCE OF PGM IN AUSTRIA.** The platinum-group minerals described here occur mainly in massive, schlieren-type chromitites within

serpentinites and serpentized dunites of the Hochgrossen ultramafic massif, Styria, and represent the first discovery of PGM in Austria. Two genetically and mineralogically distinct groups of PGM are present. The first comprises members of the Ru-Os-Ir sulphide system (laurites). These are largely euhedral and do not occur in the vicinity of secondary cracks or veinlets in the host chromites. They are, thus, considered to be cogenetic with chromite. The second group includes sulpharsenides and arsenides with irregular crystal shapes that occur interstitially with silicates and, less abundantly, within ferritichromite rims. They are attributed to secondary processes, i.e., serpentinization. 25 Refs.

## Adsorption

**080870 STUDY ON THE SORPTION BEHAVIORS OF NOBLE METALS BY BUTYLAMINE AMIDE RESIN.** The optimum conditions for separating gold from other noble metals and base metals have been studied. Most base metals are not sorbed by this resin in dilute hydrochloric acid and aqua regia solutions. Most noble metals except silver and rhodium can be sorbed completely or partially in dilute hydrochloric acid solution. Gold is strongly adsorbed for all concentrations of HCl. Successful separation has been achieved for the separation of Rh-Pd-Au and Rh-Pt-Au from each other. It is also possible to concentrate gold from seawater or different kinds of wastewater. (Edited author abstract) 6 refs. In Chinese.

## Flotation

**080872 PLATINUM GROUP AND ARSENIDE MINERALS IN COPPER-NICKEL SULFIDE BEARING DULUTH GABBRO AND THEIR FLOTATION RECOVERIES.** Reasons for low recoveries of platinum group metals have remained unresolved due to interferences in the analyses. Electron microprobe, scanning electron microscope, and scanning Auger microprobe analyses have identified nickel arsenide minerals in the ore and confirmed a close association of platinum group metals as minute inclusions. These results indicated a need for re-evaluation of flotation procedures that have ignored special problems related to arsenide minerals. The electrochemical and flotation behaviors of nickel arsenide and their application to the flotation recoveries of precious metals from copper-nickel bearing Duluth gabbro are presented. (Edited author abstract) 19 refs.

## Geochemistry

**080873 ORE DEPOSIT MODELS #12. THE PLATINUM GROUP ELEMENT DEPOSITS: CLASSIFICATION AND GENESIS.** The platinum group element deposits are subdivided within a genetic framework; the three principal deposit types are formed by (1) Orthomagmatic, (2) Alluvial or (3) Hydrothermal processes. The Orthomagmatic class can be further subdivided into three subclasses: deposits that formed as a result of (a) magma mixing, (b) contamination of magma by material from an external source, and (c) deuteric fluid activity, i.e., flow of fluids derived from the same magma as the intrusive host rocks. Hydrothermal platinum-palladium deposits include those in which a hydrothermal system has been channeled through mafic/ultramafic host rocks from which the precious metals may have been leached. (Edited author abstract) 102 refs.

Macdonald, A. James (Ontario Geological Survey, Toronto, Ont, Can). *Geosci Can* v 14 n 3 Sep 1987 p 155-166.

**Recovery** See CATALYSTS—Recovery.

## Refining

**080874 PRECIOUS REPUTATION REFINING THE EXOTICS.** The Acton refinery has a reputation as one of the world's best precious metal refineries. Platinum, palladium, rhodium, iridium, ruthenium, osmium, gold and silver are consistently produced at better than 9995+ fine. Inco began recovering precious metals (PM) identified in its Sudbury ores almost 100 years ago at a small laboratory in London, England. The nearby Acton refinery was inaugurated in 1924 to recover increasing quantities of platinum group metals (PGM). The article describes operations.

Scales, Marilyn. *Can Min J* v 109 n 6 Jun 1988 9p.

## Reviews

**080875 WORLDWIDE PGM OUTLOOK.** Platinum, iridium, osmium, palladium, rhodium, and ruthenium are known as the platinum group metals (PGM). Their unique properties, including catalytic activity, temperature and corrosion resistance, electrical conductivity and resistivity, and high purity, have promoted the use of PGM in a variety of applications in pollution control, aerospace and defense, fuel production, fertilizer production, glass and glass-fiber production, energy generation, electronics, dentistry, and jewelry. The article reviews some specific applications and examines supply and demand over the long term.

Feichtinger, F. (Int Forecasting Research Circle, S Afr); Lammer, A.; Riess, M. *Adv Mater Processes* v 133 n 4 Apr 1988 p 53-56.

## South Africa

**080876 DEMAND FOR PLATINUM.** The platinum group metals are among the scarcest of metallic elements and are critical to industry, having in the main no viable substitutes. South Africa is the Western world's major supplier, and the paper considers the action the Western world should be taking to insure against the dislocation that would arise from serious supply disruption from that source. 12 refs.

Owen, A.D. (Univ of New South Wales, Kensington, Aust). *Resour Policy* v 13 n 3 Sep 1987 p 175-188.

**080877 PLATINUM-GROUP METALS - A RESOURCE IN THE TAILINGS OF CHROMIUM MINES IN SOUTH AFRICA.** Although the concentration of platinum group elements in the LG-6 Chromitite Layer is very low - about 0.5 g/t - the minerals that contain these elements occur largely between the chromite grains. Because of their small grain size, these minerals, during washing of the ore, become concentrated together with the silicate impurities in the tailings. The platinum

group elements in the tailings are such that their extraction appears to be a profitable. It is estimated that the tailings dumps of the chromium mines in the Bushveld Complex contain close to 400,000 oz of platinum group elements, to which about 38,000 oz are added annually. (Author abstract) 12 refs.

Von Gruenewaldt, G. (Univ of Pretoria, Pretoria, S Afr); Hatton, C.J. *J S Afr Inst Min Metall* v 87 n 9 Sep 1987 p 265-268.

## Thin Films

**080878 STUDY OF THE INITIAL ALUMINIDE PHASE GROWTH IN Al/Pt COUPLES.** The thermal reaction of thin platinum films with large-grained aluminum substrates is studied with emphasis on the growth kinetics of the initial aluminate phase. In situ d.c. sputter cleaning is performed on the large-grained aluminum substrates before the platinum film is evaporated to ensure a clean interface. Uniform layer-by-layer growth of  $Pt_2Al_3$  is observed and monitored by 2 MeV  $He^+$  backscattering. The thickness  $x$  of this initial aluminate phase grows parabolically with the annealing duration  $t$  as  $x^2 = Kt$ . (Edited author abstract) 15 refs.

Zhao, X.-A. (California Inst of Technology, Pasadena, CA, USA); Ma, E.; Yang, H.-Y.; Nicolet, M.-A. *Thin Solid Films* v 153 Oct 26 1987, Pap Presented at the Int Conf on Metall Coat - Part I, San Diego, CA, USA, Mar 23-27 1987 p 379-385.

## PLATINUM MINES AND MINING

### Analysis

**080879 REVIEW OF SOME FEATURES POTENTIALLY INDICATIVE OF THE PRESENCE OF PLATINOID MINERALIZATION AS DEDUCED FROM THE STILLWATER COMPLEX, MONTANA (USA).** The Stillwater Complex of South Montana is a layered differentiated ultramafic intrusive body of late Archean age. A number of the petrological and geochemical features of the Stillwater Complex, and particularly their geometrical distributions, are of significance for the understanding of such complexes and can be used in exploration. If in a sulfide zone, 400-1000 m above the first appearance of cumulus plagioclase, one finds: the presence of chromitite layers; that olivine is the cumulus mineral in addition to plagioclase; the presence of 'pegmatoid zones' (i.e., distinct orthocumulate texture); that there is evidence of magma injection (slump textures, etc.); that the Ni/Cu ratio is greater than 1; that there is no apparent nickel depletion of the associated reef olivine; and that rare earth element abundances and ratios of plagioclase change in a way suggesting magma replenishment; then it is highly probable that such a sulfide zone has an economically interesting platinoide content. 17 refs.

van der Veen, A. (Billiton Research BV, Arnhem, Neth). *Geol Mijnbouw* v 66 n 3 1987 p 213-220.

## Developing Countries See GOLD MINES AND MINING—Developing Countries.

## Montana

**080880 STILLWATER ADDS A NEW SOURCE TO WORLD PLATINUM SUPPLIES.** The Stillwater project design was based on an initial production rate of about 100,000 oz/yr of platinum group metals, 25,000 oz of platinum and 75,000 oz/yr of palladium, contained in concentrates grading about 50 oz of pgms/st. These objectives will probably be exceeded during the first year of production. Mine and plant designers initially made provision for an expansion to 1,000 st/d by 1992, but that goal will probably be reached by 1990, or possibly sooner. Cost of the expansion is projected at \$10 million to \$12 million. The National Research Council has estimated Stillwater Mining's PGM resources above economic mining depth at 225 million oz of contained metal, Mike Sharratt, Manville senior director, mining and exploration, states.

White, Lane (Engineering & Mining Journal, New York, NY, USA). *Eng Min J* v 188 n 10 Oct 1987 p 38-43.

**080881 STILLWATER PLATINUM-PALLADIUM MINE.** The Stillwater platinum/palladium mine and mill, lies some 5 miles south of Nye, Montana. The deposit being mined to recover platinum, palladium and other precious metals is known as the J-M reef, extending over some 40 km (28 miles). Details are given of the geology, mining and mineral processing of the Stillwater ore together with an outline of some expected future developments at the site. 7 refs.

## PLATINUM NICKEL IRON ALLOYS

### Electric Conductivity

**080882 ATOMIC ORDERING AND THE ELECTRICAL PROPERTIES OF PLATINUM-NICKEL ALLOYS WITH IRON IMPURITIES.** The authors studied the influence of additions of iron on resistivity and atomic structure.  $Pt_{50}Ni_{50-x}Fe_x$  ( $x=1$ ; 5 at.%) and  $Pt_{25}Ni_{75-x}Fe_x$  ( $x=5$ ; 10; 25 at.%) were investigated. During annealing of  $Pt_{50}Ni_{50-x}Fe_x$  their temperature coefficient of resistivity rises by 25-50% whereas in  $Pt_{25}Ni_{75-x}Fe_x$  the reverse process is observed. Thus, substitution of nickel by iron changes the electrophysical properties and atomic structure. 3 refs.

## PLATINUM ORE TREATMENT

### Beneficiation

**080883 PLATINUM GROUP MINERALS IN THE DULUTH COMPLEX AND THEIR BENEFICIATION BEHAVIORS.** Platinum group metals were found in a Pt-Pd-rich zone in drill core within an oxide plagioclase olivine host rock with disseminated sulfide mineralization. Assay values showed over 9 g/t (0.27 oz per st) platinum plus palladium. The Pt-to-Pd ratio over the entire 3-m (10-ft) interval is nearly 1:1, and platinum and palladium contents show a correlation with chromium content. Platinum and palladium occur mostly as alloys and are associated with copper, nickel, and iron sulfides. Magnetic separation concentrates platinum and palladium into nonmagnetic tails. Further concentration will require special beneficiation techniques, particularly for such phases as Pt-Fe alloy. 14 refs.

Sabelin, T. (Univ of Minnesota, Minneapolis, MN, USA); Iwasaki, I.; Reid, K.J. *Trans Am Inst Min Metall Pet Eng Soc Min Eng AIME* v 280 pt A 1986 p 2122-2125.

### Flotation See Also PLATINUM METALS—Flotation.

**080884 RECOVERING PLATINUM AND PALLADIUM AT STILLWATER.** Located in southern Montana, Stillwater Mining Company is the only platinum group metals mine and flotation mill in the western hemisphere. The flotation mill, built mostly with used and reconditioned equipment, has improved to recover 93-95% of the platinum and palladium from the ore. The plant has been unavailable less than five percent of the time. (Edited author abstract) 17 refs.

Hodges, Gregg J. (Stillwater Mining Co, USA); Clifford, Roger K. *J Met* v 40 n 6 Jun 1988 p 32-35.

**080885 RECOVERY OF PLATINUM-GROUP METALS FROM GABBROIC ROCKS.** Platinum-

group metals are found mainly as arsenides, sulfarsenides, sulfides and platinum-iron alloys in gabbroic rocks. Major losses of platinum group metals in extraction most frequently occur during beneficiation. In the massive sulfide rocks of Minnesota's copper-nickel bearing Duluth Complex, platinum group minerals are in close association with arsenide minerals as inclusions. Platinum group metal recoveries from the Duluth Complex can be improved by a flotation procedure developed during an investigation with artificial nickel arsenide. This research revealed that flotation recovery of nickel arsenide is highly susceptible to oxidation. It was also found that the use of nitrogen during grinding and flotation, combined with copper activation, restores floatability. (Author abstract) 31 refs.

## PLATINUM PALLADIUM RUTHENIUM ALLOYS

### Oxidation

**080886 HIGH-TEMPERATURE OXIDATION OF Pt-45Pd-10Rh.** The surfaces of Pt-45Pd-10Rh foils oxidized over the range 875-1075 K in a 20 percent  $O_2$ -Ar mixture at atmospheric pressure were examined by Auger electron, X-ray photoelectron, and Raman spectroscopy. The composition of the oxide formed on the surface was found to vary with temperature from predominantly PdO at 875 K to  $PdRhO_2$  at 1075 K. Only a few atomic percent Pt was observed, present in both the metallic and (apparently) +1 oxidation states at 875 K and in the metallic state at 1075 K. The formation of  $PdRhO_2$  (and no  $Rh_2O_3$ ) at 1075 K was found to persist upon reoxidation following a low-temperature reduction cycle in which the increased Rh concentration on the surface was retained. An oxidation-induced Rh enrichment of the surface beyond 50 at. percent does not appear likely within the temperature/pressure regime investigated. (Author abstract). 9 refs.

Graham, G.W. (Ford Motor Co, Dearborn, MI, USA); Potter, T.J.; Weber, W.H.; Gandhi, H.S. *Oxid Met* v 29 n 5-6 Jun 1988 p 487-497.

## PLATINUM RUTHENIUM ALLOYS

**080887 PREPARATION OF HIGHLY DISPERSED Pt+Ru ALLOY CLUSTERS AND THE ACTIVITY FOR THE ELECTROOXIDATION OF METHANOL.** A new method for the preparation of Pt+Ru binary catalyst has been developed which provides a simple way of obtaining a specific surface area (ca. 80 m<sup>2</sup> g<sup>-1</sup>) more than 3 times larger than that obtained by conventional methods. This method is based on the co-deposition of fine oxides of platinum and ruthenium in atomic scale in a mixed salt solution of these metals followed by reduction with hydrogen bubbling. It was revealed that the binary catalyst prepared by this method forms alloy clusters of their solid solution, in which platinum atoms are replaced by ruthenium atoms on the lattice points of a face-centered cube in the region of Ru/Pt ratios less than 0.75. The supported alloy on carbon black exhibited an extremely high catalytic activity during the electrooxidation of methanol; i.e. ca. 200 mA cm<sup>-2</sup> at 0.4 V and a limiting current of more than 1 A cm<sup>-2</sup> when Ru/Pt=1/1. From a comparison of the relationship between the composition of the alloy and the activity with that of an ad-electrode Having ruthenium ad-atoms with a well-defined coverage, it was concluded that the composition of the alloy cluster surface is

probably the same as that of the cluster bulk. (Author abstract) 20 refs.

## PLATINUM VANADIUM ALLOYS

### Phase Diagrams

**080889 Pt-V (PLATINUM-VANADIUM) SYSTEM.** The author reviews previous work on the system. In addition to the invariant melting temperatures of the pure elements, there is an azeotropic melting maximum in the system near 27 at.% V and 1805°C. There are also one peritectic reaction, one eutectic reaction, three eutectoid reactions, and three congruent transformations in the solid state. A tabulation of these invariant reactions with temperatures and compositions is given. The review also covers crystallography, lattice parameters, thermodynamic properties and phase relationships. 38 refs.

Smith, J.F. (Iowa State Univ, Ames, IA, USA). *J Alloy Phase Diagrams* v 4 n 1 Jan 1988 p 5-13.

## PLATINUM ZIRCONIUM ALLOYS

### Internal Oxidation

**080890 MORPHOLOGY, STRUCTURE AND STABILITY OF THE OXIDE PHASE IN INTERNALLY OXIDIZED ALLOYS OF THE PLATINUM-ZIRCONIUM SYSTEM.** Platinum and its alloys are widely used for the preparation of glass apparatus. Platinum alloys strengthened by particles of stable refractory compounds, in particular oxides, are promising in this respect. The authors investigated the structure and morphology of alloys containing 0.2-2.0% Zr. Both the dispersed and the larger precipitates consist of two modifications of ZrO<sub>2</sub> - tetragonal and monoclinic. Since during use the material is in contact with air and a glass melt, the stability of the oxide phase during annealing in those two media for 1-100 hr at temperatures from 1200 to 1700°C was also studied. 11 Refs.

**080891 HOW TO KEEP VACUUM TOILETS TROUBLE FREE.** It is more than 15 years since the first vacuum toilet went to sea and the most striking experience has been how well the original principles have withstood the test of time. A variety of alternative ways of creating and maintaining vacuum have been developed, mainly with a view to greater simplicity and economy. This article reviews maintenance of these units.

Jonsson, G. (Electrolux-Enviovac). *Holl Shipbuild* v 35 n 9 Nov 1986 p 56-57.

**080892 TORQUE REQUIRED FROM ELDERLY FEMALES TO OPERATE FAUCET HANDLES OF VARIOUS SHAPES.** Contemporary housing design for the elderly features faucet handles of various shapes in the kitchen and bath. Often the elderly users cannot properly grip the faucet handle, whose shape does not allow for sufficient torque to be developed to shut off the water flow. Twenty-three elderly females turned seven different faucet handles in the clockwise and counterclockwise direction, exerting comfortable levels of torque. The only handle that consistently allowed a torque force to be developed superior to that needed to operate working installed water faucets was a medical-type paddle. A comparison of the torque needed to terminate water flow in actual water faucets with the torque developed by the standing and seated subjects showed that the nonpaddle handles did not allow subjects to generate sufficient torque to terminate the water flow. The blunt edges of the nonpaddle handles caused substantial hand pain. (Author abstract). 6 Refs.

## Hydraulic Drive See AIRCRAFT—Hydraulic Equipment.

### Standards

**080893 PLUMBING CODES AND STANDARDS: WHAT CHANGES ARE NEEDED?** Plumbing codes and standards have become an important aspect of plumbing design. They must be constantly monitored to make sure they keep up with today's needs. Water conservation requirements have to be reconciled with sanitary and safety requirements so that optimal conditions are ensured. Some examples of mistakes committed in this respect are given. As a result, e.g., model codes now require anti-scald tub/shower valves in commercial installations. Some ideas are expressed about the future of plumbing standards and codes.

Warshaw, Peter (Delta Faucet Co, Indianapolis, IN, USA). *Consult Specif Eng* v 2 n 6 Nov 1987 p 85-87.

## Water Supply

**080894 IN SEARCH OF THE PERFECT FLUSH.** By analyzing and balancing the three flows involved, mechanical engineers are designing toilets that consume only one gallon of water per flush instead of five. Various toilet designs are discussed. The optimal bowl for gravity-fed designs are evaluated. Cost-savings incentives of the various models are also aspects considered.

## PLUTONIUM AND ALLOYS See Also ATMO-SPHERIC RADIOACTIVITY—Paris, France; NUCLEAR REACTORS, PRESSURIZED WATER—Cores.

**080895 STUDIES OF A LIQUID ANODE FOR PLUTONIUM ELECTROREFINING.** A solvent anode is being developed as an alternate method for producing plutonium metal of high purity by an electrorefining process. The goal is to produce metal of 99.98% purity with an anode residue containing less than 2% of the plutonium in the feed material. If successful, a design and demonstration of a system utilizing semi-continuous and remotely controlled operations will follow. Establishing a solvent anode method should lead to improved yields and a substantial reduction in the amount of residues generated by the electrorefining process. The new method should be a viable pyrochemical technique for recovering both plutonium and uranium from spent reactor fuel. (Edited author abstract) 12 refs.

### Applications

**080896 PLUTONIUMWIRTSCHAFT - SCHLAGWORT ODER REALITAET? [Plutonium Economy - a Catch Phrase or Reality?].** The laws of physics make plutonium a necessary reality in tapping nuclear power by splitting the atomic nuclei of uranium. Plutonium is an unavoidable component of the flows of nuclear materials, but in no way the undesired by-product of nuclear economy it is frequently said to be. Plutonium is a valuable nuclear fuel, the systematic utilization of which admittedly requires that spent fuel elements be reprocessed on a technical scale but which, in this way, also offers the key to the immense energy potential contained in the uranium reserves. There is agreement on the need to handle plutonium with the utmost care. However, this also applies to other radionuclides and to chemically toxic substances as well. Proper handling techniques allow the problems arising from the use of plutonium to be managed safely. In addition, there is the widespread international control, in which national and international surveillance measure supplement and intensify each other. (Author abstract) In German.

### Electrodeposition

**080897 PREPARATION OF A <sup>238</sup>Pu STANDARD SOURCE. I. ISOTOPE DILUTION ALPHA-RAY SPECTROMETRY USED FOR STANDARDIZATION.** A <sup>238</sup>Pu source was prepared by electrodeposition method. For the standardization of the source, isotope dilution alpha-ray spectrometry (IDAS) was investigated. The content of <sup>238</sup>Pu in a sample solution was determined both by IDAS and by isotope dilution mass spectrometry (IDMS) using a standard reference material of <sup>239</sup>Pu as a spike. The estimated uncertainty in the determination of <sup>238</sup>Pu is 0.13 percent for IDAS, and the factor of IDAS/IDMS is calculated to be 1.000±0.00015. (Author abstract). 13 Refs.

Shinohara, Nubuo (JAERI, Tokai-mura, Jpn); Kohno, Nobuaki. *Nucl Instrum Methods Phys Res Sect A* v A270 n 2-3 Jul 15 1988 p 239-242.

**080898 PREPARATION OF A <sup>238</sup>Pu STANDARD SOURCE. II. SOURCE PREPARATION AND STANDARDIZATION.** A standard source of <sup>238</sup>Pu was prepared for calibrating the counting efficiency of al-

pha-ray detector. The plutonium was electrodeposited on a platinum or tantalum disk using isopropyl alcohol-hydrochloric acid solution as an electrolyte. The absolute activity was certified by isotope dilution alpha-ray spectrometry. Several types of the source, whose areas  $^{239}\text{Pu}$ -deposited are from 2.0 to 25.0 mm in diameter, were also prepared by the method. The overall uncertainties of the certified values for the standard sources prepared are estimated to be within 0.15 to 0.25 percent ( $\sigma$ ). (Author abstract). 5 refs.

## Environmental Testing

**080899**  $^{239,240}\text{Pu}$  IN ESTUARINE AND SHELF WATERS OF THE NORTH-EASTERN UNITED STATES. The distribution of  $^{239,240}\text{Pu}$  between dissolved and particulate forms has been measured in four estuaries on the north-east coast of the United States (Connecticut River, Delaware Bay, Chesapeake Bay, and Mullica River). The data cover the whole salinity range from freshwater input to shelf waters at 35‰ and includes one profile from a nearly anoxic basin in the Chesapeake Bay. In the organic-rich Mullica River estuary, large-scale removal of riverine dissolved  $^{239,240}\text{Pu}$  occurs at low salinities due to salt-induced coagulation, a mechanism analogous to that for iron and humic acids. Within the 0 to 25-30‰ zone in the other three estuaries, the activity of dissolved  $^{239,240}\text{Pu}$  increases almost conservatively. The dissolved  $^{239,240}\text{Pu}$  activity within each estuary appears to be inversely related to the flushing time of water. Dissolved  $^{239,240}\text{Pu}$  activities are lower in the nearly-anoxic bottom waters of Chesapeake Bay indicating enhanced removal by redox transformation of Pu. Additional study results are discussed. (Edited author abstract) 40 refs.

**080900** PLUTONIUM AEROSOL GENERATION IN REDUCING AND OXIDIZING ATMOSPHERES AT HIGH TEMPERATURES. Delta-phase plutonium metal pellets and foils were heated at 450°C in reducing atmospheres (3%  $\text{H}_2$  + 97% Ar or 3%  $\text{H}_2$  + 5%  $\text{N}_2$  + 92% Ar), and the respirable aerosols were collected and characterized. Residues of plutonium hydriding reactions were also heated at 450°C in air. The average percentage of initial radioactivity generated as respirable particles was 0.021% with a worst-case value of 0.46%. The particle size distribution of aerosols or powder residues was not related to the types of reaction atmosphere studied. These results support the conclusion that the major factors influencing the amount of particulate residues and their particle sizes are those that influence the integrity of a protective oxide layer, rather than the reducing or oxidizing nature of the reaction atmosphere. (Edited author abstract) 17 refs.

**080901** SELECTED RESULTS FOR MEASURING HOLDUP IN OXIDE HOODS AND TRANSFER LINES AT HANFORD. Physical inventories require quantifying the holdup in process equipment; one practical way of accomplishing this is measuring the gamma ray from plutonium ( $^{239}\text{Pu}$ ). Field measurements of plutonium holdup in dry plutonium oxide hoods or process transfer lines is frequently biased low, due to the possibility of heavy loading causing severe self-attenuation of the gamma rays. An experiment was performed to determine

the allowable loading limits for measuring plutonium holdup in dry oxide hoods. Field measurements of transfer lines in a plutonium production facility are frequently biased low due to the self-shielding of the holdup material. Fixed and portable gamma ray measurements were made of 6-ft-long sections of pipe. The results of this comparison are being used as a correction factor for routine field measurements of piping in the production facility. (Author abstract).

**080902** TOTAL NEUTRON-COUNTING PLUTONIUM INVENTORY MEASUREMENT SYSTEMS (PIMS) - AND THEIR POTENTIAL APPLICATION TO NEAR REAL TIME MATERIALS ACCOUNTANCY (NRTMA). A radiometric method of determining the inventory of an operating plutonium plant is described. An array of total neutron counters distributed across the plant is used to estimate hold-up at each plant item. Corrections for the sensitivity of detectors to plutonium in adjacent plant items are achieved through a matrix approach. This paper describes our experience in design, calibration and operation of a Plutonium Inventory Measurement System (PIMS) on an oxalate precipitation-plutonium finishing line. Data from a recent trial of Near-Real-Time Materials Accounting (NRTMA) using the PIMS are presented and used to illustrate its present performance and problem areas. (Edited author abstract).

**080903** MGA2: A ONE-DETECTOR CODE FOR RAPID HIGH-PRECISION PLUTONIUM ISOTOPIC MEASUREMENTS. The MGA (Multiple Group Analysis) code which we developed several years ago required two detectors when analyzing high  $^{241}\text{Pu}$  content samples. The isotopic information, which was obtained from the 300-kev regions, can now be obtained equally well from the low-energy region (50-208 kev). This breakthrough was achieved by developing a unique and highly accurate method for delineating the overall 'intrinsic' efficiency curve, including the plutonium K-shell absorption edge discontinuity. Consequently, the intense 129- and 148-kev peak intensities can now be used reliably in place of the peaks in the 300-kev regions to determine the relative abundances of  $^{239}\text{Pu}$  and  $^{241}\text{Pu}$ . The 203/208- and 148/152-kev pairs, and all of the intense 94- to 104-kev peaks, are included in the analysis to provide accurate data for the other isotopes of interest. (Author abstract) 10 refs.

**080904** MEASUREMENT CONTROL PROGRAM FOR CALORIMETERS AND GAMMA ISOTOPIC INSTRUMENTS. The combination of the calorimetry and plutonium isotopic measurements to determine the total plutonium mass nondestructively has become increasingly more important at the Los Alamos Plutonium Facility. A measurement control program has been developed and implemented for these two types of systems. The program serves two major functions. It provides a near real-time check of the instrumental bias and precision. It also provides a data base for monitoring the systematic and random errors associated with each instrument. At the present, there are six calorimeters and four isotopic systems operating under this program. This paper describes the measurement control program and presents an assessment of 2 years of data from the 10 instruments. (Author abstract) 3 refs.

## Recycling

**080905** PLUTONIUM RECYCLING IN FRANKERICH. [Plutonium Recycling in France]. In the plans for the expansion of nuclear power in France it was foreseen until 1980 that the extensive program of PWR plants would be supplemented by the fast breeder line around the turn of the century. Consequently, the use of plutonium was considered chiefly with a view to LMFBRs. Plutonium recycling in PWRs seemed to be less important by comparison. Now that it is becoming obvious that the large scale introduction of the LMFBR line will be delayed also in France, it was meaningful to revise the plans on how to use plutonium. Under the present economic conditions, and in view of the investments already made, plutonium recycling in PWR power plants has been found to be the most economic solution. Electricite de France therefore has focused entirely on this line and is developing a complete program based on this concept. (Edited author abstract) In German.

**Reduction** See Also URANIUM AND ALLOYS—Reduction.

**080906** REPERCUSSIONS OF THE RADIATION AND EFFECT OF CERTAIN POLYVALENT IONS ON THE ELECTROCHEMICAL REDUCTION OF  $\text{Pu(VI)}$  IN AQUEOUS SOLUTIONS. Considerable attention has centered in recent years on the development of electrochemical methods of stabilizing the valence forms of uranium, plutonium, and neptunium in the extraction processes for reproducing spent nuclear power-plant fuel, primarily with a view to a reduction in the volumes of liquid radioactive wastes and their solutes content. In this paper are set out the results of a study of the electrochemical reduction of  $\text{Pu(VI)}$  to  $\text{Pu(IV)}$  in aqueous nitric acid solutions under the effect of ionizing radiation in the presence of uranium and certain fission products (palladium, ruthenium, and technetium). The research was carried out in a temperature-controlled electrochemical cell with a titanium cathode (2 cm<sup>2</sup>) and a platinum anode (0.4 cm<sup>2</sup>) and no division between the electrode compartments. 10 refs.

**Solutions** See URANIUM COMPOUNDS—Trace Analysis.

**PLUTONIUM COMPOUNDS** See Also RADIOACTIVE WASTES—Disposal.

**080907** NEUTRON SCATTERING AND MAGNETIZATION STUDIES OF PLUTONIUM MONOCHALCOGENIDES. Magnetic susceptibility  $\chi(T)$  measurements have been performed on single crystals of  $\text{PuS}$ ,  $\text{PuSe}$ , and  $\text{PuTe}$ . For  $T > 50 \text{ K}$ ,  $\chi(T)$  is independent of  $T$  with a small value of approx.  $300 \times 10^{-6} \text{ emu/mol}$ . For  $T < 50 \text{ K}$  increases are seen in  $\chi$ . We believe these arise because of defects in the lattice. Polarized neutron diffraction has been used to determine the form factor of 5f electrons around the Pu ion. The largest induced moment is approx.  $5 \times 10^{-3} (\mu\text{B})$  so the form factor is not accurately determined, but is clearly different from that found in the localized  $\text{PuSb}$ . The results are discussed in terms of our present understanding of the Pu monochalcogenides. A theory consistent with all the present measurements is not yet available. (Author abstract) 29 refs.

## Dissolution

**080909 DISSOLUTION OF  $\text{PuO}_2$  IN  $\text{HNO}_3$ -HF- $\text{N}_2\text{H}_4$  MEDIUM.** The dissolution of plutonium dioxide ( $\text{PuO}_2$ ) in nitric acid is an extensively studied subject in view of its importance in nuclear fuel reprocessing and scrap recovery. The thermodynamic solubility of  $\text{PuO}_2$  in nitric acid has been calculated, taking into account the formation of higher nitrate complexes of plutonium at higher acidities. The dissolution of  $\text{PuO}_2$  in nitric acid containing hydrofluoric acid and hydrazine has been studied. The results indicate that the presence of hydrazine in nitric acid containing hydrofluoric acid aids the dissolution of  $\text{PuO}_2$ . The destruction of hydrazine after the dissolution step is found to be easy. 11 refs.

## Measurements

**080910 ATTRIBUTES MEASUREMENTS BY CALORIMETRY IN 15 TO 30 MINUTES.** An analysis of the early portion of the power-history data collected with both of the IAEA's air-cooled bulk calorimeters has demonstrated that such calorimeters can measure the power from preheated containers of plutonium oxide with an accuracy of 2-5% in 15 to 30 minutes. Material accountability at plutonium facilities has a need for such a capability for measurement of Pu scrap. Also, the IAEA could use just two calorimeters and a gamma-ray assay system for reliable variables and attributes measurements of plutonium mass during a two-day physical-inventory verification (PIV) at a mixed-oxide (MOX) fuel-fabrication facility. The assay results would be free of the concerns about sample moisture, impurities, and geometry that previously have limited the accuracy of assays based on neutron measurements. (Author abstract) 3 refs.

## Oxidation

**080911 STUDIES ON RADIOLYTIC OXIDATION OF PLUTONIUM (III) IN HYDROCHLORIC ACID MEDIUM.** The effect of  $\gamma$  radiation on plutonium (III) was studied in argon and oxygen equilibrated hydrochloric acid solutions. The initial G values of Pu (IV) and  $\text{H}_2\text{O}_2$  were found to be  $6.5 \pm 0.6$  and  $4.0 \pm 0.4$  respectively in oxygen equilibrated  $0.8 \text{ mol dm}^{-3}$  HCl solutions. While the G(Pu (IV)) increased to  $8.0 \pm 0.8$  in  $9.0 \text{ mol dm}^{-3}$  HCl solutions, G( $\text{H}_2\text{O}_2$ ) decreased to  $2.5 \pm 0.3$ . In argon equilibrated  $0.8 \text{ mol dm}^{-3}$  HCl solutions, the G values of Pu (IV) and  $\text{H}_2\text{O}_2$  were  $5.0 \pm 0.4$  and  $0.6 \pm 0.1$  respectively. It was observed that the initial yields of Pu (IV) decreased beyond a dose of  $6 \pm 0.1$  respectively. It was observed that the initial yields of Pu (IV) decreased beyond a dose of  $6 \times 10^{18} \text{ eV cm}^{-3}$  and there was incomplete oxidation of Pu (III) in  $0.8 \text{ mol dm}^{-3}$  HCl in both oxygen and argon equilibrated solutions, whereas Pu (III) in  $9.0 \text{ mol dm}^{-3}$  HCl was completely oxidized to plutonium (IV) in oxygen equilibrated solutions. The observed radiolytic

yields of Pu (IV) and  $\text{H}_2\text{O}_2$  are discussed in terms of reactions of Pu (III) with radiolytic products of water. Formation of a brown peroxy complex was observed in oxygen equilibrated solutions of Pu (III) in  $0.8 \text{ mol dm}^{-3}$  HCl. (Edited author abstract) 14 refs.

Nagar, M.S. (BARC, Bombay, India); Natarajan, P.R. *Radiat Phys Chem* v 30 n 3 1987 p 169-172.

**080912 KINETICS AND OXYGEN PRESSURE DEPENDENCE OF THE HIGH TEMPERATURE OXIDATION OF Pu-1WT.%Ga.** Oxidation of Pu-1wt.%Ga was measured between 150 and  $500^\circ\text{C}$  in oxygen pressures of 0.004 - 500 Torr. Three stages of oxidation were identified beyond the initial oxide nucleation. The effect of temperature on oxidation rates was determined at an oxygen pressure of 500 Torr. A discontinuity was observed between 300 and  $370^\circ\text{C}$  that resulted in a change in the activation energy for the Stage II and III processes. Oxygen pressure effects were measured at 200, 300 and  $400^\circ\text{C}$ . Both the parabolic rates for Stage I and the linear rates for Stage II were independent of pressure below 60 Torr and directly proportional to pressure above 60 Torr. Stage III was an interface reaction created by cracked and spalling of the oxide. (Edited author abstract) 28 refs.

## Radioactivity

**080913 STUDY OF IN-LINE PLUTONIUM ISOTOPIC ANALYSIS FOR GASEOUS PLUTONIUM HEXAFLUORIDE.** In-line plutonium isotopic analysis of gaseous plutonium hexafluoride ( $\text{PuF}_6$ ) is very important for process control and special nuclear material accountability in any plutonium isotope separation process that requires a gaseous phase. Although much effort had been devoted to analyze arbitrary plutonium samples, no isotopic analysis had been done on gaseous  $\text{PuF}_6$  samples. We have initiated a study on the use of a high-resolution, gamma-ray spectroscopy technique to analyze gaseous plutonium hexafluoride. For the first time,  $\text{PuF}_6$  gas samples with pressures varying from 0.15 to 31 torr, which were directly fed into a gas cell from a process flow loop, were measured. (Edited author abstract) 5 refs.

## PLYWOOD

### Adhesion

**080914 INSPECTION OF INTERIOR ADHESION IN PLYWOOD BY MEANS OF ACOUSTIC EMISSION.** A trial inspection was made of interior adhesion in plywood using the acoustic emission (AE) method. A bending test investigated the relation between AE characteristics and samples with and without adhesion in plywood. It was found that for sample C without adhesion AE started to count at an early stage of mechanical load. Also, sample C gave various amplitudes in the range from 30 kHz to 100 kHz even at an early stage of mechanical load. (Author abstract) 1 ref.

## Computer Aided Manufacturing

**080915 REAL TIME ADJUSTMENT OF PLYWOOD GLUE APPLICATION WITH A COMPUTER-CONTROLLED SPRAYLINE.** The capability of rapidly adjusting glue application rate offers several advantages in plywood production and laboratory test panel fabrication. A computer-controlled laboratory sprayline is described and tested. The described system provides accurate and rapid adjustment of glue application rate for test panel fabrication. Controlling flow rate through the spray nozzle by itself is not adequate to control glue application rate. Varying the flow properties of the glue mix affects the dispersion of the spray fan and the proportion of overspray. The actual measured application rate, used as feedback information, is necessary to maintain accurate and adjustable glue application control. (Author abstract) 11 refs.

Faust, Timothy D. (Univ of Georgia, Athens, GA, USA). *For Prod J* v 38 n 1 Jan 1988 p 35-41.

## Environmental Testing

**080916 WEATHERING PERFORMANCE OF FINISHED SOUTHERN PINE PLYWOOD SIDING.** Southern pine plywood siding with both roughsawn and scratch-sanded surfaces was finished with different commercial and laboratory-prepared materials and exposed outdoors on vertical test fences in Madison, Wis., Olympia, Wash., and Saucier, Miss. With one exception, transparent natural finishes gave reasonable performance for only 1 to 4 years. The transparent stain provided protection and, except for face checking, performed well for 5 years. Semitransparent and solid color stain finishes gave much better performance than transparent stains and protected roughsawn southern pine plywood for more than 7 years, but did not prevent face checking. The best finishes for southern pine plywood were acrylic latex paints, especially when applied over stain-blocking acrylic latex primer. A water-repellent preservative pretreatment improved the performance of the paints to a small extent and reduced face checking when an acrylic latex topcoat was used over an alkyl primer. Additional aspects of the study are discussed. (Edited author abstract) 22 refs.

Feist, William C. (USDA, Madison, WI, USA). *For Prod J* v 38 n 3 Mar 1988 p 22-28.

## Manufacture

**080917 TRANSIENT AND FREQUENCY RESPONSE ANALYSIS OF A GLUE APPLICATION CONTROL SYSTEM FOR PLYWOOD MANUFACTURING.** The objective of this study was to test a current spray application control system for transient and frequency response characteristics to determine if variable application rate control is feasible by simply converting the software. Transient response parameters of rise time, overshoot, settling time and steady state error were measured. The system performed well below acceptable levels even with modifications made to the control valve. The modifications did, however, improve system performance significantly. Frequency response tests indicated that in worst case conditions the control system could only output 38% of the control system input. (Edited author abstract) 11 refs.

## PNEUMATIC TUBES

**080921 RELATION BETWEEN THE POWDER CHARGE AND THE SHAPE OF THE PIPE IN PNEUMATIC CONVEYANCE.** The electrification of a polymer powder transported through U-bend pipes was studied at particle speeds of  $v = 17.6$  m/s and 26.4 m/s, and a solid load  $\rho = 0.017$  kg/m<sup>3</sup>. The charge/mass ratio,  $q$ , of powder passing through the U-bend pipes (seven different radii of curvature) depended on the flow pattern of the powder particles after their first collision with the inner wall of the bend of the pipe. (Author abstract) 3 refs.

Masui, Noriaki (Science Univ of Tokyo, Noda, Jpn). *Jpn J Appl Phys Part 1* v 27 n 4 Apr 1988 p 696-697.

**Applications** See IRON AND STEEL ANALYSIS—Sampling.

## Fluid Dynamics

**080922 BOUNDARY ELEMENT PREDICTION OF THE FREE SURFACE SHAPE BETWEEN TWO PARTICLE PLUGS IN A HORIZONTAL PNEUMATIC TRANSPORT PIPELINE.** A method is presented to predict the shape of the gas-particle interface between two plugs of cohesionless particles conveyed pneumatically through a horizontal pipeline. The method assumes that the moving solids are in a state of limiting equilibrium at the interface and that, therefore, the interfacial slope depends on the normal fluid pressure gradient which can be used as a boundary condition for the numerical solution of Laplace's equation. The height of stationary material between the plugs cannot be predicted by the method, since this material is not in a state of limiting equilibrium. However, an analogy with a gas-liquid system can be used to predict this height. The

method as presented is restricted to plugs of constant voidage and to systems which obey Darcy's law (packed bed Reynolds numbers less than 10). The boundary element numerical technique is used to apply the method to a 2-dimensional example of flow through a 50 mm I.D. pipe. The predictions are qualitatively in agreement with photographs of the observed shape in the true (3-dimensional) situation. However, further numerical and experimental work on the 3-D situation is required for a full assessment of the proposed method. (Author abstract) 16 refs.

**080924 SEAL FOR PNEUMATIC APPLIANCES.** The operational characteristics of pneumatic appliances are determined to a large extent by the design of the sealing units of the sliding joints. Rubber seal rings of T-shaped cross-section are reliable and long lasting in service since only a small friction force is generated when they operate. When the air pressure rises, the ring slides along the surface of the cylinder and is thrust against the wall of the groove, and it then moves together with the piston.

Alekseev, V.P.; Galimullina, A.P. *Sov Eng Res* v 7 n 3 Mar 1987 p 71-72.

**080925 DENSE-PHASE TRANSPORT: VERTICAL PLUG FLOW.** The transport of coal particles at low velocities by forming plugs was studied in a 0.0254-m vertical pipe. The pressure drop and plug velocity were measured at different air flow rates and for different plug lengths. The conditions to produce stable plugs were studied. The pressure drop was found to be independent of the air flow rate and to vary linearly with plug length. The plug velocity was independent of plug length in the conditions studied. A model that predicts the pressure drop was in good agreement with the experimental data. It suggests that in the case of vertical plug flow at low velocities, gravitational forces are the most important ones. (Edited author abstract) 15 refs.

**080926 ON A LINEAR PNEUMATIC DAMPERS. [On a Linear Pneumatic Dampers].** In the present paper a linear pneumatic damper is studied. This damper is a linear pneumatic oscillator having an auxiliary chamber commonly called a plenum chamber. This allows the gas to flow into and out of the chamber to dissipate energy without loss of gas. The root-locus of the characteristic equation is discussed in detail for several values of system parameters. The results are plotted in the complex plane with  $j\omega$  as ordinate and  $\sigma$  as abscissa. The damping ratio as a function of the parameters of the system is also determined. (Author abstract). 1 Ref. In Romanian.

## Components

**080927 VENT PNEUMATIC ENCLOSURES FOR SAFETY.** The last twenty years have seen significant growth in the practice of mounting pneumatic components within sheet metal enclosures. The movement has been spearheaded by moving part logic, where the only practical way to assemble a control system has been to mount the components in an enclosure. In fact, most user specifications require this practice to protect MPL devices from dirt, oil mists and other ambient airborne contaminants. Another important trend is the combination of electronics and low-power, miniature 3-way solenoid valves - mounted on electronic racks, again in enclosures - to provide low-capacity, high-pressure signals either directly to miniature actuators or to the air pilots of larger power valves out on the machine.

## Measurements

**080929 NEW LINEAR PNEUMATIC SENSOR FOR DISPLACEMENT MEASUREMENTS.** A simple design method for the measuring nozzle face profile of a new linear pneumatic sensor for displacement measurements is given. The procedure is efficient and produces a specially designed nozzle face profile that allows a significantly elongated linear range of the characteristic curve for the simple sensor type. There is some shifting of the experimental linear range compared with the theoretical results. (Edited author abstract). 4 Refs.

## Robot Applications

**080930 DEVELOPMENT OF THE PLACEMATE PNEUMATIC ROBOT.** Initial work on microcomputer-controlled pneumatics began in 1974. The start of the robot project dates back to 1976 when the first version of the Placemate was exhibited. The aim of the project was to design a low-cost point-to-point handling machine which would be provided with a flexible teachable capability. Such a robot would be placed above the pick and place unit, which allows only a limited number of positions to be set on each axis by means of mechanical stops (e.g. Electrolux Senior). 5 refs.

**080931 LIQUID-HELIUM SCINTILLATOR AS A FAST-NEUTRON POLARIMETER.** A liquid-helium neutron polarimeter was constructed and successfully used for polarization measurements in (p,n) and (d,n) reactions. Its effective analyzing power was about 0.7, in good agreement with a Monte Carlo calculation which includes the effects of multiple scattering and the finite size of the scatterer and the detectors. The response of the liquid-helium scintillator to neutrons was measured between 3 and 18 MeV. A linear relation was observed between the incident neutron energy and the maximum light output. No significant position dependence of the light output was found. (Author abstract) 19 refs.

**080932 POLARIZERS AND POLARIMETERS IN THE X-UV RANGE.** The advantages of polarized light were largely in the visible range as opposed to the X-UV range where no polarizer was available. Using the new X-UV multilayers set at a 45° angle of incidence it is now possible to demonstrate how such polarizers work. One is now able to measure the obtained polarization rate, compare it to the theoretical value and check the influence of the material index. Description and performances of a polarimeter using such X-UV polarizers are given. (Author abstract) 16 refs.

## Design

**080933 ACCOUNTING FOR THE EFFECT OF ANISOTROPY OF AN INSTRUMENT WHEN STUDYING SPECTROPOLARIZATION CHARACTERISTICS OF NATURAL FORMATIONS.** Polarization characteristics of solar radiation scattered or reflected by natural objects carries information on the state and properties of an object that can be used in remote-sensing studies. We consider a technique for determining and accounting for the effect that the polarization properties of an instrument has on the parameters of radiation incident on the detector when a polarization mask is placed between the detector and the monochromator. This methodology was used for designing the MSS-2P spectropolarimeter on board the Salyut-7. The small size of the device and its simplicity were achieved because the analytic polarization block was positioned near the output slit of the monochromator. These advantages are of decisive value in many situations, especially onboard spacecraft. The optokinematic schematic of the MSS-2P spectropolarimeter is illustrated. 9 refs.

Zaitseva, V.A.; Kononovich, S.I.; Plyuta, V.E. *J Appl Spectrosc* v 46 n 2 Feb 1987 p 177-182.

**080934 NEW TYPE OF POLARIMETER FOR VECTOR- AND TENSOR-POLARIZED DEUTERONS FOR APPLICATIONS IN INTERMEDIATE ENERGY GRAPHICS.** The design, the construction and the calibration of a high-efficiency deuteron polarimeter for the simultaneous measurement of the vector polarization  $i_{11}$  and the tensor polarization  $t_{20}$ ,  $t_{21}$  and  $T_{22}$  is described. It is based on the  $^3\text{He}(d,p)^4\text{He}$  reaction and is capable to measure the polarization of secondary low intensity deuteron beams (50-1000 deuteron/s) produced in nuclear and particle physics. The usable deuteron energy range is between 15 and about 100 MeV. The calibration of the polarimeter shows only a small sensitiv-

ity with respect to the energy, position and angle of the incident deuterons. The polarimeter is particularly able to work in a high background. (Author abstract) 22 refs.

## Imaging Techniques

**080936 CHARGE-COUPLED-DEVICE-BASED IMAGING POLARIMETER FOR ASTRONOMY.** Using a thinned, three-phase Texas Instruments 800×800 CCD (TI 3PCCD) and inexpensive plastic Polaroid material, we have constructed an imaging polarimeter for astronomical data collection. A unique method of image shifting, shuttering, and Polaroid rotation enables us to circumvent the sky transmission fluctuations that normally plague polarimetry. The method is possible only because of the exceedingly low dark current and exceedingly high charge-transfer efficiency of this CCD. Our observations of standard polarimetry stars have verified the operation of our imaging polarimeter and have demonstrated that polarimetry can be accurately performed below the 1% polarization level with well-behaved CCDs. (Author abstract) 12 refs.

**080937 DIFFERENTIAL PULSE POLAROGRAPHIC STUDIES OF COPPER(II)-POLYAMINE COMPLEXES AT LOW LIGAND CONCENTRATIONS.** The application of differential pulse polarographic (DPP) experiments at low ligand concentration to the characterization of complexes has been investigated by studying three previously characterized copper(II)-polyamine systems. The DPP results were compared to cyclic voltammetry (CV) and cyclic differential pulse voltammetry (CDPV) measurements as well as to simulations. The Cu(II)-ethylenediamine system at a 1:1 concentration exhibits three DPP peaks. This is shown to be due to direct reduction of the complexes. In the case of Cu(II)-triethylenetriamine, direct observation of two protonated complexes is possible at a 1:1 concentration upon titration with strong acid. The results for Cu(II)-diethylenetriamine appear consistent with values of  $\log \beta_1 = 16$  and  $\log \beta_2 = 21$ , although detailed studies of this system were precluded by a polarographic maximum. (Author abstract) 17 refs.

## POLES

### Concrete

**080942 PRODUCTION AND ERECTION OF PRESTRESSED CONCRETE POLES FOR A RAILROAD ELECTRIFICATION PROJECT.** A long line production method for producing prestressed concrete poles to support overhead catenary wires for a railroad electrifica-

tion project has been developed in New Zealand. The method is ideally suited to producing poles economically from a conventional multiproduct pretensioned precast concrete factory using semiskilled labor. This paper describes the evolution of the design concept, optimum pole shapes, quality assurance, production and installation methods. (Author abstract)

McSaveney, Leonard G. (Firth Industries Ltd, Auckland, NZ). *PCI J* v 32 n 5 Sep-Oct 1987 p 42-51.

**080943 DESIGN CONSIDERATIONS FOR TAPERED PRESTRESSED CONCRETE POLES.** A strength design procedure based on the ACI 318-83 Building Code is developed for circular hollow-cored and I-shaped prestressed concrete poles and is implemented in a microcomputer program for an IBM PC. Load-moment interaction diagrams are automatically generated for any input values of the main variables. Three types of prestressing tendons with nonlinear stress-strain relations are considered. The effects of tendon configuration and other design parameters such as type of prestressing tendon, average prestress, concrete compressive strength and reinforcing index are evaluated. Nondimensionalized design charts for prototype conditions are presented. 12 refs.

## Design

**080944 RELATIVE ECONOMICS OF PRESTRESSED CONCRETE POLES.** Prestressed concrete poles have found increasingly wide acceptance due to their viability as a factory produced unit. Advantages offered by prestressed concrete over other materials justify its usage for poles. With the popularity of using prestressed concrete poles, many manufacturers and designers are continuously trying to select a shape of pole which is economical and practical to manufacture. The shape of prestressed concrete pole reflects on the economy to manufacture it. Taking into account the limits of sizes and strengths normally used and the relative economics of manufacturing, the most widely used four shapes are discussed in this paper. (Author abstract) 5 refs.

Sharma, O.P. (Hong Leong Industries Manufacturing Ltd, Singapore). *J Inst Eng India Part CI* v 68 Jan 1988 p 204-207.

## Painting

**080945 COST EFFECTIVE MAINTENANCE PAINTING.** In street lighting poles maintenance cost effective painting schemes which tolerate a degree of substrate deterioration after the initial service period, and/or which give long durable service, should be the objective of all painting specifications. However, such objectives cannot be achieved if painting method and choice of material is left to the tenderer, and if specifications do not take cognizance of the condition and exposure environment of plant items. Salient fundamentals and practical factors as outlined herein have significant effect on selection of a maintenance painting regime. The paper assumes that there is an economic case for maintenance painting, and discusses the use of paint systems to meet certain criteria. The choice from a large number of materials/types can be rationalized if all the salient factors and criteria are assessed. Additionally, the choice of paint manufacturer can be equally difficult. 2 refs.

## Wood

**080949 FIELD EVALUATION OF FOUR WOOD POLE GROUNDLINE PRESERVATIVE FORMULATIONS USING WESTERN CANADIAN WOOD SPECIES.** The objective of the study was to determine whether copper-8-quinolinolate, copper naphthenate or bis(tributyltin) oxide (TBTO) are equivalent to pentachlorophenol in extending the service life of utility poles in western Canada, when applied as a groundline 'in situ' treatment using the pressure spade. Stubs prepared from utility poles were installed in a test plot and pressure spade treated with the four preservative greases. The preservative content of each pole stub was determined prior to remedial treatment and after one and three years of exposure. Bioassays on core samples removed from the stubs assessed changes in the protection against standard wood destroying fungi. Based upon both the chemical retention data and the bioassays, it was concluded that either copper naphthenate or TBTO, or even a mixture of both, could be used as alternatives to pentachlorophenol for use in grease remedial treatment. (Edited author abstract) 22 refs.

Ruddick, J.N.R. (Forintek Canada Corp, Vancouver, BC,

Can). *Res Rep Can Electr Assoc* n 068 D 129 May 1987 var pagings.

**080950 MANAGING AMERICA'S WOOD POLE INVENTORY.** Utilities manage more than 100 million wood power poles from coast to coast. New treatment, inspection, and repair processes are enabling the industry to significantly extend the life of this multibillion dollar resource. This paper discusses safer preservatives for new poles, extending pole life better repair techniques, pole diagnostics and nondestructive testing. 5 refs.

Shepard, Michael; Kennon, Richard; Ng, Harry; Shula, William. *EPRI J* v 12 n 6 Sep 1987 p 30-37.

**080951 BENDING PERFORMANCE OF SPLICED, NAILED-LAMINATED POSTS.** This study investigated the effect of three splice variables on post stiffness and bending strength. These variables - splice length, splice location, and the presence or absence of a reinforcing metal nail plate - were evaluated by comparing their relative effect on post stiffness and strength. Increasing the splice length and adding a nail plate had the greatest individual effects on strength and stiffness, while splice location showed little relative effect on post bending performance. Interactions between variables also affected bending performance to some extent. For instance, strength and stiffness were less affected by the presence of a nail plate when a 1,220-mm (4-ft) splice was used compared to a 610-mm (2-ft) splice. Implications of the study results are discussed. (Edited author abstract) 18 refs.

Winistorfer, S.G. (Univ of Wisconsin-Madison, USA); Moody, R.C.; Cramer, C.O. *Trans ASAE* v 30 n 6 Nov-Dec 1987 p 1791-1796.

**080952 DEVELOPMENT OF AN ENVIRONMENTALLY ACCEPTABLE WOOD POLE GROUNDLINE PRESERVATIVE FORMULATION.** Many Canadian electrical utilities carry out groundline remedial preservative treatment on aged wood utility poles using a pentachlorophenol based grease. A program was undertaken to identify an environmentally acceptable wood pole preservative formulation which would meet or exceed the performance criteria of present pentachlorophenol formulations. Copper naphthenate was considered to be a suitable replacement for pentachlorophenol. Groundline preservative formulations incorporating copper naphthenate at a concentration of 2% as copper metal are expected to provide protection against decay for ten years to poles originally pressure treated with oilborne or waterborne preservatives. Copper naphthenate is a low toxicity preservative, not known to harm humans, animals, or plants and is registered as a general use wood preservative with Agriculture Canada and the United States Environmental Protection Agency. (Edited author abstract) 12 refs.

Hawthorne, S. (Ontario Hydro, Toronto, Ont, Can). *Res Rep Can Electr Assoc* 068-D-129B Nov 1987 var pagings.

**080953 ELECTRICAL CHARACTERISTICS OF WOOD POLES.** An assessment procedure has been developed to evaluate the hazards resulting from contact with wood poles. A general computer based wood pole model accounting for treatment penetration, moisture content gradients, and rain was developed from field and laboratory measurements. The relative safety of five wood pole species treated with three treatments has been evaluated under several contact scenarios. Generally, penta and untreated poles result in higher degrees of safety, from the viewpoint of body current during personnel contact with the pole, than do similar poles treated with either CCA or ACA waterborne preservatives. (Edited author abstract)

**Electrolytic** See Also METAL FINISHING; STAINLESS STEEL—Polishing; STEEL—Machining; STEEL—Polishing.

**080956 KINEMATICS OF PLANETARY EROSION AS A BASIS FOR ELECTRO-DISCHARGE POLISHING AND PROCESS OPTIMISATION STRATEGIES.** The advantages of EDM polishing are to be found chiefly in the multidirectional processing of complex volumes without the undercuts which easily arise with manual polishing in tool- and mould-making. A considerable number of individual factors affect the polishing process, with decisive effects on the product quality which can be achieved. Particular importance may be ascribed to such pulse parameters as discharge current, pulse duration, pulse interval, open-circuit voltage and polarity, which must be carefully matched if a shining polished surface is to be achieved. (Edited author abstract) 10 refs.

Koenig, W. (RWTH, Aachen, West Ger); Joerres, L.; Behmer, U. *Adv Manuf Processes* v 2 n 1-2 1987 p 23-35.

**080957 ANODIC LEVELLING OF MODEL PROFILES WITH PULSATING CURRENT.** The rate of anodic levelling with pulsating current is being investigated with triangular model profiles made of nickel using a flow channel cell. Observed results are compared to theoretical calculations of the rate of anodic levelling of macroprofiles and of microprofiles under d.c. conditions. It follows that the rate of anodic levelling is smaller above the pulse-limiting current density than that below it, and is smaller than that predicted for an ideal macroprofile. With pulsating current the rate of levelling of macroprofiles did not depend on profile orientation with respect to electrolyte flow. (Author abstract) 11 refs.

## POLONIUM

## Chemical Reactions

**080959 NEUTRALIZATION KINETICS FOR POLONIUM-218.** In a well-defined experimental system the neutralization of polonium-218 ions was investigated as a function of the physical and chemical properties of the controlled composition atmosphere. The diffusion coefficient of polonium-218 under various concentrations of trace gas NO<sub>2</sub> in nitrogen was measured. The mobilities of Po<sup>+</sup> and PoO<sub>2</sub><sup>+</sup> are determined by combining experimental results with a computer model of the system. Three neutralization mechanisms were individually studied. The small-ion recombination rate has been found to be proportional to the square root of radon concentration. The electron-scavenging mechanism is responsible for the neutralization of Po<sup>+</sup> in NO<sub>2</sub> or H<sub>2</sub>O in nitrogen. When PoO<sub>2</sub><sup>+</sup> is formed, the electron-transfer mechanism dominates the neutralization process. (Edited author abstract) 30 refs.

## POLYACENES

## Phase Diagrams

**080960 FEIERLIS PHASES IN POLYACENE.** Polyacene (C<sub>4</sub>H<sub>2</sub>)<sub>x</sub> is a conjugated polymer which consists of two strongly coupled polyacetylene chains. The structure of polyacene may be regular with equal bond lengths (PA1), or distorted with alternating bonds (PA2 and PA3) or different bond lengths in both chains (PA4). The PA3 and PA4 phases are quantitatively compared within a simple tight-binding model, and a phase diagram is calculated. It is shown that PA3 phase is favored for some suitably chosen sets of the relevant parameters. 10 refs.

**POLYACETYLENES** See Also POLYMERS—Conductive.

**080961 LIVING NON-CONJUGATED POLYACETYLENES.** The non-conjugated poly (3,3-dimethyl-1-butyne) and poly (1-trimethylsilyl)-1-propyne were prepared by metathesis catalysts and the polymerization was monitored for molecular weight by gel permeation chromatography (GPC) and monomer conversion by GC. Both the 1-(trimethylsilyl)-1-propyne and 3,3-dimethyl-1-butyne gave a linear relationship with number average molecular weight versus conversion and number average molecular weight versus monomer to initiator ratio. The 1-(trimethylsilyl)-1-propyne failed to polymerize beyond 100% conversion. The 3,3-dimethyl-1-butyne, however, gave conversion to 300%, with GPC data clearly showing the continuation of propagation from the living polymer chain. The living character of these polymerizations seems to be the result of both the lack of backbiting which can occur only from a cis-cisoidal growing chain, and the lack of interchain reactions. (Edited author abstract) 15 refs.

**080962 SOLITONS IN POLYACETYLENE.** Polyacetylene is presented both as a prototype conducting polymer and as a prototype one-dimensional metal and semiconductor. The concepts of the physics of one-dimensional metals are demonstrated on idealized polyacetylene. A review of the chemical and physical properties of real polyacetylene is given and experimental results on electrical conductivity, magnetic behavior, optical spectroscopy and photoconductivity are discussed in the context of soliton-like excitations. (Author abstract) 500 refs.

Roth, Siegmund (Max-Planck-Institut fuer Festkoerperforschung, Stuttgart, West Ger); Bleier, Hartmut. *Adv Phys* v 36 n 4 Jul-Aug 1987 p 385-462.

**080963 CALORIMETRIC METHOD FOR DETERMINING THE ISOMER CONTENT OF POLYACETYLENE.** The change in enthalpy associated with the cis to trans isomerization of polyacetylene films has been measured by differential scanning calorimetry (d.s.c.) and compared with the initial isomer content determined by FTIR. The data indicate a linear relation independent of sample history, making calorimetry a convenient means to assess the gross isomerism of this material. (Author abstract) 7 refs.

Tober, R.L. (Univ of Texas at Dallas, Richardson, TX, USA); Ferraris, J.P. *Polym Commun (Guildford Engl)* v 28 n 12 Dec 1987 p 342-343.

**080964 NEW LOCALIZED MODE OF SOLITON AND THE INFRARED ABSORPTION IN POLYACETYLENE.** A new localized mode of soliton called 'staggered mode' is found for the first time, which is infrared active and has a peculiar vibration configuration in which all the odd atoms are fixed whereas the even atoms oscillate in alternate directions. It is proved by our theory that there only exist three infrared active localized modes around the soliton in polyacetylene. The results show that these three infrared active localized modes conform with the observed infrared absorption lines of 900, 1988 and 1395 cm<sup>-1</sup>. (Author abstract) 14 refs.

**080965 NORMAL VIBRATIONAL ANALYSIS OF CIS-POLYACETYLENE.** The normal vibrational calculation was carried out on cis-polyacetylene (PA) and its model compound, cis, trans-2, 4-hexadiene. Based on the observed IR and Raman frequencies, force constants relevant to the cis-structure were refined. Finally a force field common for cis-PA, trans-PA and three model molecules was obtained. The observed spectra of cis-PA were theoretically assigned and the similarities and differences between the cis- and trans- conjugate systems were discussed on the basis of normal coordinate calculation. (Author abstract) 10 refs.

Wang, Jianling (Acad Sinica, Changchun, China); Jing, Xiabin; Feng, Zhiliu. *Chin J Polym Sci (Engl Ed)* v 5 n 4 1987 p 308-315.

**080966 NORMAL VIBRATIONAL ANALYSIS OF TRANS-POLYACETYLENE.** The results of normal vibrational analyses of trans,trans-2,4-hexadiene and the backbone of trans,trans-1,4-diphenyl-butadiene were used in the normal mode computation of trans-polyacetylene (PA). Only 8 non-zero calculated frequencies were obtained which obeys the rule of 3N-4. The potential energy distribution (PED) data were in good agreement with the empirical assignment of Shirakawa et al. and Kuzmany, but most of the vibrational frequencies of trans-PA had contributions from several empirical modes, indicating the more complicity in trans-PA molecular vibration than in the model molecule case. The calculated C=C and C-C stretching frequencies of trans-PA were over 200 cm<sup>-1</sup>

higher and lower than the observed ones, respectively, due to the longer effective conjugate length in the trans-PA. (Edited author abstract) 19 refs.

**080967 PHOTOINDUCED ABSORPTION OF GAP STATES IN IODINE-DOPED POLYACETYLENE.** We have studied steady-state photoinduced absorption in trans-[CH(I<sub>2</sub>)<sub>x</sub>]<sub>n</sub> from 0.1 eV to 2.5 eV. In the lightly-doped semiconducting phase we have found evidence for interband gap increase with doping, in accordance with the soliton lattice model. The photogenerated charged defects in the heavily-doped metallic phase are characterized by two correlated absorption bands and infrared-active vibrations. (Author abstract) 18 refs.

**080968 COULOMB CORRELATIONS IN ONE-DIMENSIONAL CONDUCTORS WITH INCOMMENSURATE BAND FILLINGS AND THE SEMICONDUCTOR-METAL TRANSITION IN POLYACETYLENE.** The one-dimensional Hubbard and Hubbard-Peierls models are studied for various regimes of band filling. A variational ansatz for the ground state is worked out for small values (on the scale of the bandwidth) of the on-site Coulomb interaction. It is shown that this term enhances the lattice dimerization in the half-filled band case, but suppresses the lattice distortion in the incommensurate case. The semiconductor-metal transition in doped polyacetylene is tentatively attributed to this effect. Parameter values extracted from properties of the undoped material yield a critical dopant concentration of about 3%. (Author abstract) 22 refs.

**080969 FIRST PRINCIPLES INVESTIGATION ON THE VALIDITY OF THE PEIERLS MECHANISM FOR THE DIMERIZATION ENERGY OF TRANS-POLYACETYLENE.** Detailed general potential linearized augmented plane-wave calculations indicate that interchain interactions in trans-polyacetylene drastically lower the density of states near the Fermi level in the symmetric (undimerized) state. This is in fact a model-independent result arising solely from interchain coupling and the non-symorphic symmetry group of the three-dimensional unit cell. Local density total-energy studies indicate that the interchain interactions reduce the strength of the Peierls mechanism so strongly that this mechanism may not provide the majority of the symmetry-breaking force as it is generally believed to do. (Author abstract) 13 refs.

**080970 MODEL CALCULATIONS OF POLYMER HETEROSTRUCTURES: QUANTUM WELLS IN CONJUGATED MOLECULAR CHAINS AND SPACER MOLECULES IN 'MOLECULAR WIRES'.** In this contribution, the authors calculate the energy band structure and the corresponding eigenfunctions of polymer heterostructures on the basis of the Hückel theory. The existence of localized states can be shown for two different model structures. The first model represents a cyclic chain built up of polyacetylene (PA) and polydiacetylene (PDA) units. The content of PA molecules in PDA is varied from 0-100%. In a wide concentration range discrete split-off states appear within the energy gap of the heterostructure, which due to their localization behavior

can be identified as quantum-well states. The structure of these quantum-well states is strongly influenced by bond alternation defects. The second model describes a benzene ring embedded in a finite PA chain. The energy structure is calculated and criteria are derived on whether or not the benzene ring can act as a spacer molecule. 3 refs.

## Aging

**080972 AGEING OF ELECTRICALLY CONDUCTING ORGANIC MATERIALS.** Ageing with respect to conductivity has been investigated for a wide variety of organic materials ranging from polyacetylene and polypyrrole salts to carbon black and carbon fibers, which are conducting materials in their electrically neutral state. For two polyacetylenes of different composition and a polypyrrole phenylsulfonate the influence of temperature on conductivity and its change with time could be described quantitatively. Data on the stability of polypyrrole salts under humidity and under extreme inert conditions are given. The influence of the degree of oxidation on the stability under ambient conditions is reported for a polypyrrole perchlorate. (Edited author abstract) 7 refs.

Muenstedt, H. (BASF AG, Ludwigshafen, West Ger). *Polymer* v 29 n 2 Feb 1988 p 296-302.

## Applications See Also ELECTRODES—Materials.

**080973 APPLICATION OF SUBSTITUTED POLYACETYLENES TO SEMIPERMEABLE MEMBRANES - THE POSSIBILITY OF LOOSE RO MEMBRANE.** As an application of substituted polyacetylenes, poly(1-phenyl-2-chloroacetylene) (PPCA) which exhibits excellent thermal and chemical durability, was fabricated into asymmetric UF membranes by the conventional phase inversion method. A characteristic feature of the PPCA UF membrane was its lower molecular weight cut-off properties. When the content of acetone in the dope as a non-solvent to PPCA increased, the molecular weight cut-off value of the PPCAS membrane lowered. Another characteristic was that it could be sulfonated directly by immersion into fuming sulfuric acid. The resulting charged membrane had lower molecular weight cut-off properties than the non-sulfonated ones. The salt rejection properties were ascribed to the effect of the Donnan membrane equilibrium. (Edited author abstract) In Japanese. 11 refs.

**080974 APPLICATION OF SUBSTITUTED POLYACETYLENES TO SEMIPERMEABLE MEMBRANES - THE POSSIBILITY OF HOLLOW FIBER TYPE MEMBRANES.** As an application of substituted polyacetylenes, poly(1-phenyl-2-chloroacetylene) (PPCA) has been fabricated into hollow fiber type UF membranes and a module was prepared. Striking contrasts were observed between the hollow fiber type and the flat sheet type membranes as to the effect of a poor solvent in the dope on such membrane characteristics as flux and rejection. A tentative explanation of the phenomenon was made. The effect of spinning conditions such as the dope

feeding rate, inner solution rate, and towing rate on the size of hollow fibers were elucidated. The scale up of the module revealed that the feeding rate of the test solution to be separated could be an essential factor for the effective use and design of the module. This pilot module also showed an excellent separation of a mixture of poly(ethylene glycol)s of molecular weights 1000 and 6000. (Edited author abstract) In Japanese. 3 refs.

## Calculations

**080975 CALCULATION OF LOCALIZED VIBRATIONAL MODES AROUND A SOLITON IN TRANS-POLYACETYLENE USING THE MOLECULAR ORBITAL METHOD.** Vibrational frequencies of polyacetylene with a charged soliton are calculated for finite chain lengths using the molecular orbital method. A translational mode, an amplitude oscillation mode, a third localized mode and a staggered mode are obtained as localized modes. It is found that the frequency of the translational mode is inversely proportional to the square of the chain length, and approaches zero when the length becomes infinite. This can be explained if the soliton is regarded as a quantum particle in a box. A type of electron-hole symmetry holds, even with the Coulomb effect, between occupied orbitals of the cation and unoccupied orbitals of the anion and between unoccupied orbitals of the former and occupied orbitals of the latter. (Author abstract) 26 refs.

## Computer Simulation

**080976 ANALYTICAL ENERGY GRADIENTS FOR DYNAMICAL SIMULATIONS OF TRANS POLYACETYLENE CHAINS WITHIN THE PARISER-PARR-POPLE HAMILTONIAN.** Exact analytical energy gradients for the Pariser-Parr-Pople (PPP) Hamiltonian are derived. A comparison of computer times for dynamical simulations of trans-Polyacetylene (t-PA) using analytical and numerical gradients is given. The numerical method is shown to lead to serious difficulties both computationally and from the point of view of numerical accuracy. Using the analytical method, it turned out that the computational effort for the gradient calculation is negligible compared to that for the SCF iteration in each time step of a simulation. Using the numerical method the gradient calculation is the time consuming bottleneck of a simulation. A previously presented method for the gradient calculation in the Hückel type Su-Schrieffer-Heeger (SSH) Hamiltonian, which was thought to be approximative, is shown to be exact. (Edited author abstract) 18 refs.

## Defects

**080977 CONFORMATIONAL DEFECTS IN DURHAM POLYACETYLENE: PHOTO-INDUCED IR ABSORPTION.** We report here steady state photo-induced absorption (PA) measurements using an IBM Instruments (Bruker) vacuum Fourier transform spectrometer on stretch-oriented and unoriented films of Durham polyacetylene. For the stretch-aligned samples, we find that the energies of both the vibrational and the electronic absorption features are similar to those measured in 'long-chain' Shirakawa material, but for the unoriented films we find that the photo-induced charged solitons are more strongly pinned and have a larger dynamic mass. 35 refs.

## Degradation

**080979 STABILITY AND DEGRADATION OF SOME ELECTRICALLY CONDUCTING POLYMERS.** The oxidative degradation reactions of polyacetylene, prepared from a soluble precursor polymer, are described and compared with those of more common polymers and of polyacetylene prepared by the conventional method. Doping to low levels with electron acceptors removes the electrons involved in oxygen doping and the polymer becomes much more stable in air. Doping to high levels leads to new instabilities as the polymer reacts slowly with its counter-ions. Studies of polypyrrole and polythiophene show that these polymers are much more stable than polyacetylene but still undergo degradation reactions. The general features of their degradation mechanisms are discussed. (Edited author abstract) 35 refs.

## Dielectric Properties

**080980 FREQUENCY DEPENDENCE OF THE LARGE, ELECTRONIC  $\chi^{(3)}$  IN POLYACETYLENE.** The third order optical susceptibilities ( $\chi^{(3)}$ ) of trans- and cis- $(CH)_x$  have been determined in the spectral region below the gap by measuring the third harmonic generation efficiency. The magnitude of  $\chi^{(3)}$  parallel to the polymer chains in trans- $(CH)_x$  is in excess of  $10^{-9}$  esu for wavelengths larger than 1.3  $\mu m$ , and the spectrum of  $\chi^{(3)}$  in trans- $(CH)_x$  has a sharp two-photon resonance at an energy corresponding to half the semiconducting gap. Both the off resonance and the two-photon resonance enhanced values of  $\chi^{(3)}$  are explained by a simple band picture. (Author abstract) 18 refs.

Kajzar, F. (CEA, Gif-sur-Yvette, Fr); Etamad, S.; Baker, G.L.; Messier, J. *Solid State Commun* v 63 n 12 Sep 1987 p 1113-1117.

## Diffusion

**080981 DIFFUSION IN CONDUCTING POLYMERS.** The diffusion of oxidizing dopant gases into polyacetylene films has been studied. The process is complicated because it is influenced by the doping reaction, by swelling of the polymer by the gas and by degradation reactions of the polymer with the counter-ions. Electrochemical measurements of anion and cation diffusion in doped polymer give diffusion coefficients comparable with those for gaseous dopants. Diffusion coefficients for ions in polythiophene are reported. The results are discussed in terms of potential applications of these polymers. (Author abstract) 24 refs.

**080982  $AlCl_3$ -ASSISTED FORMATION OF CHARGE-TRANSFER COMPLEXES BETWEEN POLYACETYLENE AND TETRACYANOETHYLENE, TCNE.** Polyacetylene,  $(CH)_x$ , the simplest conjugated polymer, can be converted into a conducting

material ( $8 \Omega^{-1} cm^{-1}$ ) by treating it with a TCNE  $AlCl_3$ /benzene solution. An electron transfer  $\pi$ -complex was obtained, as shown by EPR and XPS spectroscopies. (Author abstract) 10 refs.

Kulziewicz-Bajer, I. (CNRS, Vandoeuvre-les-Nancy, Fr); Billaud, D. *Synth Met* v 22 n 3 Jan 1988 p 239-245.

**080983 EFFICIENCY, STABILITY AND SELF DISCHARGE OF ELECTROCHEMICALLY-DOPED POLYACETYLENE IN PROPYLENE CARBONATE ELECTROLYTE.** Discrepancies between the estimates of doping level of electrochemically-doped polyacetylene,  $[CH]_x$ , obtained by coulometry and elemental analysis, suggest that a significant fraction of charge is consumed in the oxidation of electrolyte. This coulombic inefficiency of charging leads to a net inefficiency on cycling. The stability of p-type  $[CH]_x$  is much greater than that of n-type  $[CH]_x$  in propylene carbonate electrolyte. In the absence of impurities and lithium, the stability of p- $[CH]_x$  is much higher than had been previously estimated for  $[CH]_x$  in batteries. The self-discharge rate in propylene carbonate is lower for high concentrations of electrolyte. A mechanism for self discharge by oxidation of solvent is presented. (Edited author abstract) 35 refs.

Schlenoff, Joseph B. (Univ of Massachusetts, Amherst, MA, USA); Chien, James C.W. *Synth Met* v 22 n 4 Feb 1988 p 349-363.

**080984 SEGMENTED POLYACETYLENE,  $(CHD)_x$ ; ELECTROCHEMICAL n-DOPING STUDIES.** Defects involving  $sp^3$  hybridized carbon atoms in the form of (HCD) units have been controllably introduced into trans- $(CH)_x$  by chemical methods to produce polymers of the type trans- $(CHD)_y$ , i.e.,  $[(CH)_{1-y}(HCD)_y]_x$  ( $y=0, 0.15$  and  $0.17$ ), in order to study the nature of these defects and their effect on the electronic and magnetic properties of trans- $(CH)_x$ . The effects of these defects on the electrochemical reduction (n-doping) of trans- $(CHD)_y$  up to 4.0 mol % reduction levels have been studied. The results are consistent with optical and Raman spectra of trans- $(CHD)_y$  species and are interpreted as showing that: (i) the band gap in trans- $(CHD)_y$  is essentially unchanged from that in trans- $(CH)_x$  because of a small but significant amount of long conjugated sequences remaining in the deuterated polymer; (ii) the maximum density of states near the conduction band edge has moved upwards from the band edge; and (iii) the (HCD) defects are clustered rather than randomly spaced in a given  $(CHD)_y$  chain. (Author abstract) 43 refs.

Wan, Mei Xiang (Univ of Pennsylvania, Philadelphia, PA, USA); Arbuckle, Georgia A.; MacDiarmid, Alan G.; Epstein, Arthur J. *Synth Met* v 24 n 4 Jun 1988 p 283-299.

**080985 IN SITU ELECTRON SPIN RESONANCE EXPERIMENTS ON POLYACETYLENE DURING ELECTROCHEMICAL DOPING.** We present results obtained from in situ e.s.r. measurements on both n-type and p-type materials during electrochemical doping. For the n-type data were obtained over an extended concentration range out to about 15 mol % (or well into the metallic regime); for p-type  $[(CH)^+y(CIO_4^-)_y]_x$  we have succeeded in achieving doping levels sufficiently high in situ to observe the abrupt first-order onset of the Pauli spin susceptibility. Comparison of the results obtained from p-type and n-type electrochemical doping shows remarkable similarities between the two. The precise symmetry of the results obtained from n-type and p-type doping demonstrates without ambiguity the charge conjugation symmetry of trans- $(CH)_x$ . The mechanism for the first-order electronic phase transition is discussed. (Edited author abstract) 29 refs.

Chen, J. (Univ of California, Santa Barbara, Santa Barbara, CA, USA); Heeger, A.J. *Synth Met* v 24 n 4 Jun 1988 p 311-327.

**080986 DOPING OF POLY(acetylene) TO THE METALLIC STATE USING THIONYL CHLORIDE.** In this report, the reaction of  $(CH)_x$  with vapor and liquid phase thionyl chloride to produce conductive poly(acety-

lene) films is described.  $SOCl_2$  is a highly oxidizing, volatile liquid that can be easily removed under dynamic vacuum following the reaction.  $SOCl_2$  has been found to be an effective oxidant for poly(acetylene), increasing the electrical conductivity by several orders of magnitude. The oxidized  $(CH)_x$  sites are thought to be compensated with chloride ion liberated by reduction of  $SOCl_2$ . 14 refs.

Calvert, Jeffrey M. (US Naval Research Lab, Washington, DC, USA); Pehrsson, Pehr E.; Milliken, Joann; Weber, David C.; Brant, Patrick; Nowak, Robert J. *Synth Met* v 25 n 2 Aug 1988 p 197-202.

**080987 KINETICS OF ELECTROCHEMICAL n-DOPING OF POLYACETYLENE INVESTIGATED BY IMPEDANCE AND GALVANOSTATIC PULSE MEASUREMENTS.** The characteristics of n- and p-doping of polyacetylene in different solvents were investigated by potentiostatic and galvanostatic charge/discharge curves, the fast Fourier transform impedance method and the galvanostatic pulse technique. The intercalated ions were  $Li^+$ ,  $Na^+$ ,  $ClO_4^-$  and  $BF_4^-$ . From the impedance measurements a rapid determination of electrochemical parameters like double-layer capacitance, electrolyte resistance and polarization resistance at different states of charge and discharge were obtained. Similarly, electrode kinetics and diffusion behavior were determined by the galvanostatic pulse technique. The doping characteristics were additionally monitored by in situ resonance Raman scattering experiments. We found strong evidence for solvent coinjection during the doping process. Ion diffusion is rate controlling to a much higher degree for undoping compared to n-doping. (Author abstract) 14 refs.

Nagele, G. (Univ Wien, Vienna, Austria); Nauer, G.E.; Kuzmany, H.; Kuerti, J. *Synth Met* v 21 n 3 Oct 1987, Proc of the Conf on Electron Processes in Conduct Polym, Part III, Vadstena, Swed, Aug 18-20 1986 p 293-299.

**080988 ELECTROINTERCALATION OF IIIB METAL CHLORIDES  $MCl_4$  INTO POLYACETYLENE.** The electrochemical doping of polyacetylene with  $MCl_4^-$  anions ( $M=Ga, In, Tl$ ) was carried out in order to evaluate the potentials of doping and degradation, the reversibility of the reactions and the maximum doping level in each system. A parallel x-ray study performed on the three  $[CH(MCl_4)_x]$  compounds leads to the proposition of an intercalation model that is supported by the electrochemical data. Electrical resistivity and EPR measurements have been analyzed as a function of the doping level and the temperature. (Author abstract) 8 refs.

Jourdan, P. (Univ de Nancy I, Vandoeuvre-les-Nancy, Fr); Ghanbaja, J.; Billaud, D. *Synth Met* v 24 n 1-2 Apr 1988, Proc of the Second Fr-Pol Colloq on Low Dimens Org Conduct and Electroactive Polym, Nancy, Fr, May 12-15 1987 p 15-22.

**080989 TRANSPORT AND SPIN RESONANCE IN n-DOPED POLYACETYLENE.** The EPR parameters and the electrical conductivity of vapor phase alkali metal-doped polyacetylene have been examined as a function of the doping level and temperature. Based on the calculations of Koder relating the shape of the EPR signal to the dynamic parameters of the spins responsible for these signals, the evolution of  $T_D$ , the diffusion time of the paramagnetic centers through the skin depth, is discussed. The temperature dependence of the electrical conductivity of heavily-doped trans- $(CH)_x$  is compared with our previous data concerning compounds synthesized from cis-rich  $(CH)_x$ . A  $\sigma=AT^\alpha$  relationship is confirmed over a wide temperature range with  $\alpha < 1$ . (Author abstract) 14 refs.

Billaud, D. (Univ de Nancy I, Vandoeuvre-les-Nancy, Fr); Ghanbaja, J.; Marche, J.F.; McRae, E.; Goulon, C. *Synth Met* v 24 n 1-2 Apr 1988, Proc of the Second Fr-Pol Colloq on Low Dimens Org Conduct and Electroactive Polym, Nancy, Fr, May 12-15 1987 p 23-30.

**080990 ELECTRONIC AND STRUCTURAL PROPERTIES OF ALKALI-METAL-DOPED POLYACETYLENE: SOME e.s.r. STUDIES.** In this paper we try to unify the description of the properties of alkali-metal-doped polyacetylene samples that can be deduced from e.s.r. measurements. We point out the importance of the structural modifications appearing during doping on the observed behavior. In some cases staging has been evidenced, but in all cases the electronic properties are intimately related to the structural properties. (Author abstract) 10 refs.

Bernier, P. (GDPC-USTL, Montpellier, Fr); Rachdi, F.; El-Khodary, A.; Fite, C. *Synth Met* v 24 n 1-2 Apr 1988, Proc of the Second Fr-Pol Colloq on Low Dimens Org Conduct and Electroactive Polym, Nancy, Fr, May 12-15 1987 p 31-33.

**080991 RAMAN SCATTERING OF DOPED POLYACETYLENE.** Experimental and theoretical results obtained by resonance Raman scattering on doped polyacetylene are presented. In the case of n-doped samples, it is shown that new vibrational mode are observed in the experimental resonance Raman scattering spectra at 1276  $\text{cm}^{-1}$  and 1600  $\text{cm}^{-1}$ . From a theoretical point of view, these features are interpreted as new vibrational modes induced by the perturbation of the chain by the dopant. This leads to an increase of the force constants with respect to the unperturbed system. The behavior of the new bands is discussed as a function of the dopant level and the exciting wavelength. Differences between n- and p-doped systems are shown and explained in terms of electronic properties induced by the dopant. (Author abstract) 20 refs.

Mulazzi, E. (Univ de Nantes, Nantes, Fr); Lefrant, S.; Faulques, E.; Perrin, E. *Synth Met* v 24 n 1-2 Apr 1988, Proc of the Second Fr-Pol Colloq on Low Dimens Org Conduct and Electroactive Polym, Nancy, Fr, May 12-15 1987 p 35-40.

**080992 GROUND STATE OF DOPED POLYACETYLENE.** The Su-Schrieffer-Heeger model and its extensions applied to doped polyacetylene are reviewed. It is shown that a solitonic lattice is always most stable and that there is a gap in the electronic structure even at high concentrations of dopants. (Author abstract) 5 refs.

**080993 METALLIC TEMPERATURE DEPENDENCE OF CONDUCTIVITY IN HEAVILY-DOPED POLYACETYLENE.** We have studied the temperature dependence of conductivity in heavily  $\text{FeCl}_4^-$ ,  $\text{ClSO}_3^-$  and  $\text{AsF}_6^-$ -doped polyacetylene films by means of the ordinary four-probe and voltage-shortened compaction (VSC) methods. The results of the VSC measurements were interpreted by saying that the intrafibril resistance of heavily-doped polyacetylene was metallic and obeyed a  $T^2$  law through the whole temperature range 1.9-300 K. (Author abstract) 39 refs.

**080994 ANISOTROPIC KINETICS OF OPTICALLY EXCITED CHARGE CARRIERS IN TRANS-POLYACETYLENE.** Transient photoconductivity in highly oriented polyacetylene has been investigated. A large anisotropy of  $\mu_{\parallel}/\mu_{\perp} \approx 50$  has been found for carrier motion parallel and perpendicular to the chains. The relaxation has been followed over 8 orders of magnitude in time, establishing directly the existence of a fast ( $\tau_f \approx 100$  ps) and a slow component (lasting up to seconds). An appreciable anisotropy has been observed with respect to the polarization of the incident light, indicating interchain charge creation as predominant

mechanism of the photoexcitation of carriers. (Author abstract) 22 refs.

**080996 DC-CONDUCTIVITY OF A NEW TYPE OF HIGHLY CONDUCTING POLYACETYLENE N-(CH)<sub>x</sub>.** We present precision conductivity measurements on a new type of stretch-aligned, iodine doped polyacetylene, yielding a room temperature conductivity  $\sigma$  of about  $80,000 \Omega^{-1}\text{cm}^{-1}$ . The temperature dependence of  $\sigma$  was investigated between 3 K and 300 K parallel ( $\sigma_{\parallel}$ ) and perpendicular ( $\sigma_{\perp}$ ) to the stretching axis using both MONTGOMERY- and standard four-probe techniques. For freshly prepared samples, the results indicate a common limiting mechanism for  $\sigma_{\parallel}$  and  $\sigma_{\perp}$  and are perfectly described by the SHENG model within the entire temperature range. Deliberate aging gives information about the influence of chemical defects on the conductivity mechanism. (Author abstract) 23 refs.

**080997 AB INITIO STUDY OF THE ROTATIONAL POTENTIAL ENERGY SURFACE OF CIS-TRANSOIDAL POLYACETYLENE.** Ab initio self-consistent field molecular orbital calculations have been performed to obtain the intramolecular rotational potential energy surface for cis-transoidal polyacetylene with simultaneous rotations about two successive single bonds. The results indicate the possibility of existence of a 'superhelix' instead of a tight  $2^3/1$  helix. Using the energy surface obtained, Monte Carlo calculations have been done to obtain the probabilities of the existence of various conformations of this polymer. (Author abstract) 17 refs.

**080998 OPTICAL SPECTRA AND OPTICAL CONDUCTIVITIES OF IODINE-DOPED POLYACETYLENE.** Reflection spectra of iodine-doped polyacetylene are studied for the wavenumber range 20-40,000  $\text{cm}^{-1}$  in order to find changes occurring in the electronic structure of the polymer upon doping. Three stages of doping are recognized from a spectral analysis of  $(\text{CHI}_3)_x$ : (1)  $0 < x < 0.10$ , where the charged soliton domain is the dominant product; (2)  $0.10 < x < 0.18$ , the free carrier is found where the hole and the unpaired electron are formed simultaneously; (3)  $0.19 < x < 0.25$ , the free carriers begin to overlap each other and metallic properties become more evident. A new type of electronic transition associated with the electron transfer (charge resonance) between the hole states is found in the far-infrared region. (Edited author abstract) 24 Refs.

**080999 INFLUENCE OF THE CONJUGATION LENGTH OF POLYACETYLENE CHAINS ON THE D.C. CONDUCTIVITY.** The dc conductivity of doped polyacetylene, into which  $\text{sp}^3$  defects have deliberately

been incorporated, is investigated. The  $\text{sp}^3$  defects were created by p-type doping and subsequent hydrolysis of polyacetylene samples. These defects shorten the effective conjugation length of the polyacetylene chains and therefore have a strong influence on the dc conductivity  $\sigma$ .  $\sigma$  has been measured in the temperature range 4 to 370 K. For both doping levels investigated (3.5% and 15% of iodine), the conductivity drops by three orders of magnitude for a concentration of 15% of  $\text{sp}^3$  defects. The shortening of the conjugation length can be verified by resonance Raman scattering. (Author abstract) 12 refs.

**081000 CONDUCTIVITY MEASUREMENTS ON DOPED POLY(SUBSTITUTED)ACETYLENES.** The attention of many authors has been focused on the electrical properties of doped polyacetylene (PA), and different theories have been developed to explain its conductivity. PA shows the simplest model for a polyenic chain and has given the best results as a conducting material upon doping. We have investigated the electrical properties of doped polyphenylacetylene (PPA), polybenzylpropargylamine (PBPA) and polyethynylferrocene (PEF) obtained by  $\text{Rh(I)}$  complexes, which are active polymerization catalysts in mild reaction conditions and give linear, soluble, air-stable polymers with a backbone similar to that of PA. **081001 NEGLIGIBLE PHOTOCONDUCTIVITY EFFICIENCY AND IMPURITY SENSITIVE ABSORPTION FINE STRUCTURE AT THE LOW-ENERGY TAIL OF  $\pi$ - $\pi^*$  TRANSITION IN TRANS-POLYACETYLENE.** Photocurrent spectra normalized by incident light intensity together with high-resolution optical absorption spectra have been obtained in the visible and near IR regions using carefully prepared very pure samples. The photocurrent efficiency is practically zero at the low energy tail of the  $\pi$ - $\pi^*$  absorption band and gradually increases with the photon energy, becoming very high on the high energy side. Oxygen doping produces a photocurrent peak at 1.4 eV and a corresponding series of sharp absorption bands which stick to the intrinsic absorption band edge. (Author abstract) 17 refs.

**Electronic Properties**

**081003 THEORETICAL ANALYSIS OF MODEL COMPOUNDS OF SUBSTITUTED POLY(ACETYLENES): CONFORMATION VERSUS ELECTRONIC PROPERTIES.** The influence of the conforma-

tion of conjugated molecules on their electronic properties has been investigated using the extended Hückel theory. Dimers of acetylene and methylacetylene have been taken as model compounds of poly(acetylene) and poly(methylacetylene). Upon increasing the torsional angle between the two repeat units, both the band gap and the ionization potential increase, but the change is more pronounced with the former variable. This increase is not regular and becomes more important at angles larger than 30°. Non-planar conformations are then expected with poly(methylacetylene) and other n-alkyl monosubstituted poly(acetylenes) and explain their large band gap (i.e. blue shifting) in comparison with that of poly(acetylene). (Edited author abstract) 26 refs.

**081005 MONTE CARLO COMPUTATION OF ELECTRONIC PROPERTIES OF POLYACETYLENE.** The ground state energy, spin and charge density waves and their correlation functions in polyacetylene are computed by the Monte Carlo method. Hubbard and Pariser-Parr-Pople models are employed and the results are compared with the valence bond calculation. The bond alternate system has a lower energy than the regular system both in Hubbard and PPP models. The Coulomb interaction beyond on-site assists in the formation of a charge density wave and suppresses the spin density wave. The soliton system has a lower energy than the regular system. (Author abstract) 18 refs.

**Film** See Also FILMS—Chemical Vapor Deposition.

**081006 SYNTHESIS AND CHARACTERIZATION OF ORIENTED POLYACETYLENE FILMS.** The physical properties of polyacetylene have been widely investigated in the last fifteen years. However, the standard Shirakawa technique provides randomly oriented fibers, so that most experimental results are averaged over the chain directions. Recently K. Araya et al. succeeded in the polymerization of oriented polyacetylene using Shirakawa's catalyst dissolved in a nematic liquid crystal. In this paper the authors compare the different methods used to achieve the liquid crystal orientation: gravitational flow, orientation induced by the glass substrate and magnetic field orientation. The properties of the resulting films were investigated by scanning electron microscopy, x-ray diffraction, polarized ir spectroscopy and dc conductivity. (Author abstract) 5 refs.

**081007 EPR STUDIES OF BINARY ALKALI**

**METAL DOPED POLYACETYLENE.** The evolution of the EPR characteristics ( $\Delta H_{pp}$ , A/B and g) of vapour phase alkali metal doped polyacetylene has been examined as a function of the doping duration and the nature of the dopant (Na, K, Rb, Cs). Different kinds of spins are responsible for the two observed signals. At intermediate doping levels, concomitant lightly and heavily doped parts of the material lead to the superposition of two signals or to an anomalous signal the form of which is discussed. For high doping levels, the linewidth  $\Delta H_{pp}$  of homogeneous samples follows a  $Z^\alpha$  law with  $\alpha = 2.9 \pm 0.5$ . Our results are compared with other data related to polyacetylene doped with alkali-metals in solvent media. (Author abstract) 20 refs.

## Measurements

**081008 NEUTRAL PHOTO-EXCITATIONS IN ORIENTED POLYACETYLENE.** Polarization-dependent measurements of photo-induced absorption (PA) have been carried out on highly oriented films of polyacetylene prepared by the Durham precursor route. For temperatures below 100 K, the PA spectrum exhibits an absorption peak at 1.36 eV, as observed for Shirakawa polyacetylene. This feature is due to a neutral excited state. The PA peak is independent of probe-beam polarization and some 200 times weaker than in Shirakawa samples. These results suggest that the neutral excitations are rendered metastable by interactions with existing structural defects in the polymer. (Author abstract) 33 refs.

## Optical Properties

**081009 OPTICAL ABSORPTION OF THE SOLITON LATTICE.** The optical conductivity for the soliton lattice solution of the continuum approximation to the Su-Schrieffer-Heeger model of doped polyacetylene is calculated for different excess electron densities. The optical sum rule is verified in each case. The resulting shifts of the absorption maxima are compared with experiment. Implications of the finiteness of  $\Delta_0/W$  (gap/bandwidth) on the nature of the phase transition and the absorption are discussed. These results are relevant to conducting polymers. (Edited author abstract) 22 refs.

Puff, H. (Akad der Wissenschaften der DDR, Berlin, East Ger); Streitzwolf, H.W. *Phys Status Solidi B* v 143 n 2 Oct 1987 p 765-775.

**081010 INFLUENCE OF PHOTOINDUCED STRUCTURAL DISTORTIONS ON INTERBAND ABSORPTION IN POLYACETYLENE.** Picosecond pump and probe experiments were carried out on fully oriented transpolyacetylene. Exciting the sample at 527 nm, photoinduced bleaching and absorption were observed at 527 nm and 1054 nm, respectively. The measurements give an upper limit of 2 ps for the relaxation time of the photogenerated 0.5 eV hot carriers to the band edges. The evaluation of the measured optical processes strongly suggests the conclusion that photoinduced structural distortions of the polyacetylene chain result in observable transient decrease of the interband absorption. This may be ascribed to the reduction of the density of electronic states and to that of the interband transition matrix element of the momentum operator. (Author abstract) 17 refs.

**081013 OPTICAL PROPERTIES OF AS<sub>2</sub>F<sub>5</sub>-DOPED TRANS-POLYACETYLENE.** Measurements of the anisotropic optical properties on AsF<sub>5</sub>-doped high-oriented non-fibrous crystalline trans-(CH)<sub>x</sub> are presented. The reflectance parallel to the chain direction shows a Drude-like behavior of strongly damped carriers and no indication of any interband contributions from undoped regions. Perpendicular to the chain direction, the reflectance is very low and constant throughout the region of the plasma edge for light polarized parallel to the chains. A Kramers-Kronig analysis of the parallel reflectance data yields the complex refractive index and allows the real and imaginary parts of the dielectric function and the optical conductivity to be deduced. (Author abstract) 2 refs.

Leising, G. (Technical Univ Graz, Graz, Austria); Filzmoser, M.; Kahlert, H. *Synth Met* v 21 n 3 Oct 1987, Proc of the Conf on Electron Processes in Conduct Polym, Part III, Vadstena, Swed, Aug 18-20 1986 p 267-270.

## Oxidation

**081014 INFLUENCE OF ADDITIVES ON THE ELECTROCHEMICAL OXIDATION OF POLYACETYLENE.** The result of the electrochemical oxidation of polyacetylene is improved by additives in the electrolyte, which suppress overoxidation of polyacetylene. The temperature dependence of the conductivity is semiconductor-like and is interpreted by Sheng's fluctuation-induced tunneling model for tunneling between metallic regions. Polyacetylene oxidized in the presence of additive (e.g., bithiophene) has a smaller intrinsic resistance of the metallic strands. (Author abstract) 7 refs.

Krische, Bernd (Royal Inst of Technology, Stockholm, Swed); Soderholm, Svante. *Synth Met* v 21 n 3 Oct 1987, Proc of the Conf on Electron Processes in Conduct Polym, Part III, Vadstena, Swed, Aug 18-20 1986 p 319-324.

## Phase Transitions

**081015 TRANSITION TO A GAPLESS PEIERLS INSULATOR IN HEAVILY-DOPED POLYACETYLENE.** At high doping concentrations, polyacetylene undergoes a transformation into a state characterized by high d.c. conductivity, by a large Pauli susceptibility and by the absence of the interband transition of the undoped polymer. The optical spectrum shows a pseudogap at  $\approx 0.2$  eV and vibrational modes which imply that the carbon-carbon bond length is not uniform. We conclude that this state is best described as a gapless incommensurate Peierls insulator. (Author abstract) 33 refs.

## Physical Chemistry

**081016 ESR STUDY OF THE SEMICONDUCTOR-METAL TRANSITION IN ALKALI DOPED POLYACETYLENE: SPECIFICITY OF THE DOPANT.** We have described and analyzed in situ ESR measurements of the electrochemical doping of cis-rich  $(CH)_x$  with Li and Na. From the continuous evolution of the linewidth ( $\Delta H_{pp}$ ) and asymmetry ratio (A/B) with the doping level, the transition from a semiconducting to a metallic state has been observed for doping with both Li and Na. A specific behavior has been observed in each case with, in particular  $\Delta H_{pp}$  increasing with the atomic number of the dopant for the metallic complexes. (Author abstract) 17 refs.

Fite, C. (USTL, Montpellier, Fr); El Khodary, A.; Bernier, P. *Solid State Commun* v 62 n 9 Jun 1987 p 599-602.

## Physical Properties

**081017 RANDOM SOLITON DISTRIBUTION IN TRANS-POLYACETYLENE.** We investigate the electronic density of states (DOS) and the localization properties of trans-polyacetylene with a random distribution of neutral narrow soliton-type defects. The problem is treated within the renormalized virtual crystal method with triplet decimation, which preserves the soliton contribution to the DOS. The localization of the state at the Fermi energy is calculated as a function of soliton concentration, cs, and our results indicate that a significant increase of the hopping conductivity may occur for  $cs - 5 - 10\%$ . (Author abstract) 21 refs.

de Melo, C.A.R. Sa (Pontificia Univ Catolica, Rio de Janeiro, Brazil); Brandi, H.S.; Koiller, Belita. *Solid State Commun* v 61 n 3 Jan 1987 p 171-176.

**081018 BIPOLARON FORMATION AND DESORPTION FOLLOWING AUGER DECAY IN POLYACETYLENE.** The Su-Schrieffer-Heeger model has been applied to a trans-polyacetylene chain with two holes at the top of the valence band. In the kink-free chain the formation of a kink-antikink pair is observed. This is deformed to a polaron pair due to end effects and the lack of dissipation in the model. In the case of an end-kink configuration desorption may occur. The influence of a substitutional NH impurity on these phenomena has been discussed. (Author abstract) 8 refs.

Liegener, C.-M. (Friedrich-Alexander-Univ Erlangen-Nuernberg, Erlangen, West Ger); Foerner, W.; Ladik, J. *Solid State Commun* a2 p 203-206.

## Production

**081019 NEW PROCESS FOR THE PRODUCTION OF METAL-LIKE, STABLE POLYACETYLENE.** An acetylene polymerization reaction catalyzed by an aged mixture of  $Ti(OC_4H_9)_4/Al(C_2H_5)_3$  in a silicone oil reaction medium yields a homogeneous, defect-free, polyacetylene film that can be stretched mechanically by up to 550%, corresponding to stretching rates of 6.5. On being doped with iodine, the film displays an electrical conductivity of  $\approx 16,000$  S/cm per unit weight. Both washed (catalyst-free) and unwashed (catalyst-containing) films were stretched. An aged mixture of  $Ti(OC_4H_9)_4/Al(C_2H_5)_3$  in silicone oil that has been mixed with various quantities of n-butyllithium and allowed to react with acetylene yields polyacetylene that is highly regular, compact and crystalline in well-defined parallel planes. This film can be stretched by up to 400% ( $1/l_0 = 5$ ) and, after doping, gives a conductivity of  $> 100,000$  S/cm per unit weight. (Author abstract) 8 refs.

## Research

**081020 PREPARATION OF POLYACETYLENE IN LOW-POLYDISPERSITY DIBLOCK AND TRIBLOCK COPOLYMERS.** There is a need for absolute control over polymer preparation, ideally to give soluble, block copolymers with as narrow a molecular weight distribution as is possible. The authors report such a method and they believe the results are most consistent with the 'aggregate' being formed by cross-linking of the polyene portions of the diblocks or triblocks, beginning when the polyene chain length reaches approximately 15. If this is the case then the implication is that Durham polyacetylene contains a significant amount of cross-linked polyene chains. These results are consistent with other reports that solubilized polyacetylene prepared by classical methods forms 'aggregates'. 12 refs.

## Spectroscopic Analysis

**081021 CHAIN LENGTH DEPENDENCE OF LOCALIZED VIBRATIONAL MODES AROUND A SOLITON IN TRANS-POLYACETYLENE.** Vibrational frequencies of finite polyacetylene with a charged soliton are calculated using the molecular orbital method. It is found that the frequency of the translational mode has a remarkable length effect and is inversely proportional to the square of chain length. The dependence is explained by regarding the soliton as a quantum particle in a one dimensional box. (Author abstract) 19 refs.

Mori, Yuhei (NTT, Tokai-mura, Jpn); Kurihara, Susumu. *Solid State Commun* v 64 n 6 Nov 1987 p 947-950.

**081022 CHARACTERISTICS OF LASER INDUCED LUMINESCENCE IN POLYACETYLENE.** Polyacetylene (PA) is the prototype conducting polymer because of the simplicity of its molecular structure. Its uniquely simple electronic structure has been a model for theoretical studies of 1-D semiconductors. Characteristics of trans- $(CH)_x$  luminescence near the interband absorption edge and the doping effect on luminescence by implanted erbium have been investigated for the first time. 7 refs.

Jin, Changqing (Acad Sinica, Changchun, China); Zhang, Xinyi. *J Lumin* v 40-41 Feb 1988, Excited State Processes in Condensed Matter, Proc of the Int Conf on Lumin, Beijing, China, Aug 17-21 1987 p 264-265.

## Spectrum Analysis

**081023 PHYSICAL MEANING OF THE CONJUGATION LENGTH IN POLYMERS.** Raman scattering experiments were performed on pristine trans-polyacetylene, on polymer samples where defects have been accommodated systematically along the chains, and on polydiacetylene. The results show that the dispersion of the satellite line strongly depends on the concentration of the defects. A calculation showed the  $sp^3$  carbons to be the most effective interruptions of the conjugation. Other physical and chemical properties like electrochemical doping, linewidth of e.s.r. signals and conductivity after doping are strongly related to the dispersion. (Author abstract) 9 refs.

Kuzmany, H. (Univ Wien, Vienna, Austria); Kurti, J. *Synth Met* v 21 n 1 Aug 1987, Proc of the Conf on Electron Processes in Conduct Polym, Part I, Vadstena, Swed, Aug 18-20 1986 p 95-102.

**Stability** See LATEXES—Synthesis.

## Structure

**081024 ANDERSON LOCALIZATION IN A POLYACETYLENE CHAIN WITH  $SP^3$  CARBON DEFECTS.** The electronic structure of a model for a polyacetylene chain with a random distribution of  $sp^3$  carbon defects is studied by the tight-binding molecular

orbital theory. The dependence of the Anderson transition near the band center (levels around the Fermi level) and in the band wings (levels near the lowest occupied and the highest unoccupied levels) on the number of  $sp^3$  carbons introduced is examined. Even one  $sp^3$  carbon in a chain leads to localization at the band edge. Near the center of the band, both the extended and the localized states co-exist densely even if the number of  $sp^3$  carbons increases. It is concluded that conduction electrons delocalize over a chain at a finite temperature as a result of the mixing of the states near the Fermi level. (Author abstract) 23 refs.

Tanaka, Kazuyoshi (Kyoto Univ, Kyoto, Jpn); Yamanaka, Shozo; Oiji, Masaki; Yamabe, Tokio. *Synth Met* v 22 n 3 Jan 1988 p 247-256.

**081025 DISPLACEMENT VECTORS OF LOCALIZED VIBRATIONAL MODES AROUND A CHARGED SOLITON IN TRANS-POLYACETYLENE.** The localized vibrational modes of finite polyacetylene with a charged soliton are calculated taking full degrees of freedom into consideration. The displacement vectors of each localized vibrational mode are obtained and shown in this report. The vectors are discussed in connection with mode mixing. The localized modes are successfully classified into branch modes of four modes: translational, amplitude oscillation, third localized and staggered. Displacement patterns of localized modes indicate that the coupling between the two types of C-C stretching branch modes is weak, but there is a strong coupling between one of the C-C stretching modes and the C-H bending mode. Calculated frequencies and infrared intensities are found to be in good agreement with the infrared spectrum. Furthermore, it has been found that a force constant matrix obtained from a short cluster model is not suitable for calculation in the case of a long polyacetylene chain. (Author abstract) 47 refs.

Mori, Yuhei (ATR Optical & Radio Communications Research Lab, Osaka, Jpn); Kurihara, Susumu. *Synth Met* v 24 n 4 Jun 1988 p 357-370.

**081026 ELECTRONIC STRUCTURE OF CONDUCTING POLYMERS: INVESTIGATIONS OF ORIENTED SAMPLES BY ELECTRON ENERGY-LOSS SPECTROSCOPY.** The electronic structure of undoped and doped oriented polyacetylene, polyparaphenylene and polyphenylenevinylene has been studied by measuring the excitations of valence-band electrons by electron energy-loss spectroscopy. (Author abstract) 21 refs.

## Synthesis

**081028 FUNCTIONAL MONOMERS AND POLYMERS. CXLVII. INCLUSION COMPOUNDS OF POLY(1,3-BUTADIENE) IN DEOXYCHOLIC ACID AND APOCHOLIC ACID CANALS: SYNTHESIS AND CHARACTERIZATION.** The inclusion polymerization of 1,3-butadiene was studied at different temperatures using deoxycholic acid and apocholic acid as the host molecules. The polymers that resulted consist of predomi-

nantly 1,4-structure rather than 1,2 or acene structure as confirmed by both IR and Raman spectroscopies. The poly(1,3-butadiyne)s were found to possess unique optical properties and high electric conductivity as compared with those prepared by the usual polymerization methods. (Author abstract) 16 refs.

Tsutsumi, Hiromori (Osaka Univ, Suita, Jpn); Miyata, Mikiji; Takemoto, Kiichi. *J Polym Sci Part A* v 25 n 11 Nov 1987 p 3079-3087.

**081029 SYNTHESIS AND CHARACTERIZATION OF POLY[*o*-(TRIFLUOROMETHYL)PHENYL]ACETYLENE.** Polymerization of *o*-(trifluoromethyl)phenylacetylene initiated by 1:1 mixtures of  $WCl_6$  or  $MoCl_5$  with various organometallic cocatalysts provided in high yields a substituted polyacetylene having weight-average molecular weight ( $M_w$ ) of  $2 \times 10^5$ – $16 \times 10^5$ . A mixture of  $WCl_6$  with  $Ph_4Sn$  was especially active as catalyst and achieved a high  $M_w$  of  $16 \times 10^5$ . The product polymer was a dark brown solid, soluble in such solvents as toluene and chloroform. A tough film could be obtained by solution casting. The polymer was thermally fairly stable in air. The high molecular weight, film formation, and fair thermal stability of the present polymer are notable characteristics, which are not seen in poly(phenylacetylene). (Author abstract) 13 refs.

**081030 SOLUBLE POLYACETYLENE OBTAINED WITH RARE-EARTH CATALYST AND SOME ASPECTS OF POLYMERIZATION MECHANISM.** Soluble polyacetylene (PA) with well-defined nature has been synthesized with catalyst system  $Nd(i-OPr)_3/AlR_3$  ( $R = C_2H_5$ ,  $i-C_4H_9$ ) and characterized by IR, Raman and ESR Spectra etc. Number average molecular weight of the soluble specimen were determined by VPO to be about 500g/mol. or lower. The IR and NMR spectra and end group analysis of the soluble polyacetylene fully demonstrate that polymerization of acetylene with rare-earth catalyst is realized through monomer insertion between the transition metal-carbon bond. **081034 PREVAPORATION SEPARATION OF ETHANOL-WATER MIXTURES USING IONICALLY CROSSLINKED BLENDED POLYACRYLIC ACID (PAA)-NYLON 6 MEMBRANES.** The pervaporation separation of ethanol-water mixtures was carried out through a series of ionically crosslinked polyacrylic acid (PAA)-Nylon 6-blended membranes crosslinked to varying degrees in aluminum nitrate solution. The polyacrylic acid (PAA)-Nylon 6 membranes were cast from homogeneous PAA-Nylon 6 mixtures to various thicknesses and then crosslinked. Optimum pervaporation results were obtained from crosslinked blends containing 75 wt percent Nylon 6 and 25 wt percent PAA. These membranes have separation factors (water/ethanol) of 35-40 at flux rates of 120-160 g/m<sup>2</sup> h. The optimum crosslinking time was found to be approximately 35 h to yield membranes with the best separation and flux rates at 25 wt percent PAA content. (Author abstract) 18 refs.

**Research**

**081036 MEROCYANINE-SPIROPYRAN PHOTO-CHEMICAL TRANSFORMATION IN POLYMERS, PROBING EFFECTS OF RANDOM MATRICES.**

Isomerization kinetics of the merocyanine-spiropyran transformation in several poly(alkyl acrylates) are detected by time-resolved absorption spectroscopy. The decay of the colored merocyanine exhibits significant deviations from first-order patterns. The energy of activation can be separated into a stabilization energy for the isomer and an activation inherent to the amorphous matrix by observing the decoloration patterns for the corresponding photoisomerization. These observations can be explained by matrix effects in the isomerization modeled by statistics and fluctuations of matrix-site energies. (Edited author abstract) 24 refs.

**Solutions**

**081037 ON THE ELECTROSTATIC CONTRIBUTION TO THE PERSISTENCE LENGTH OF FLEXIBLE POLYELECTROLYTES.** Quasi-elastic light scattering methods were used to study the dynamics of dilute solutions of high molecular weight ( $M_p = 10^7$  daltons) poly(acrylate) for  $[KCl]_{added} = 0.00, 0.05, \text{ and } 0.10 \text{ M}$ . The correlation functions were analyzed by a third-order cumulant and an overlay histogram with exponential sampling methods of analysis. The histograms exhibited a bimodal distribution. It is argued that the fast mode evident in the histograms is associated with the pure translational diffusion process for PAA-K and that the slow mode may be associated with hindered diffusion through cages found by neighboring polyions. (Edited author abstract) 40 refs.

**Synthesis**

**081038 REEXAMINATION OF THE SYNTHESIS OF LIQUID CRYSTALLINE SIDE-CHAIN POLYACRYLATES VIA LIQUID-LIQUID PHASE-TRANSFER CATALYSIS.** We have reexamined the synthesis of liquid crystalline side-chain polyacrylates under liquid-liquid phase-transfer conditions as first reported by D. Keller. Instead of the polymeric liquid crystals, the hydrolysis of the mesogen and a subsequent nucleophilic substitution reaction was found to predominate over the anticipated reaction between the carboxylate group and the mesogen. The present results are consistent with the high pH conditions prevailing in the poly(sodium acrylate) solution as determined previously. The control of the pH value in the reaction medium is perceived to be crucial in determining the reaction pathway. (Author abstract) 19 refs.

**Thin Films**

**081039 THERMAL BEHAVIOUR OF FILMS OF PARTIALLY NEUTRALIZED POLY(ACRYLIC ACID). 3: EFFECT OF MAGNESIUM AND CALCIUM IONS.** Partially neutralized polyacrylates of calcium and magnesium have unexpectedly been found not to undergo thermal decarboxylation at 250°C, unlike partial polyacrylates of lithium, sodium or potassium. Reflectance infrared spectroscopy has confirmed that the partial polyacrylate of calcium is predominantly ionic but as with the magnesium compound, this does not promote decarboxylation. Further study of the partial lithium salt of poly(acrylic acid) has confirmed that lithium ions exhibits some degree of covalency, and hence are probably site-bound. Despite this, they succeeded in promoting decarboxylation. It is concluded that the main factor which prevents calcium and magnesium facilitating decarboxylation is their divalency, rather than any inherent tendency to become site-bound. Reasons for this are discussed. (Author abstract) 17 refs.

**Waste Disposal**

**081041 ENVIRONMENTAL BEHAVIOR OF <sup>14</sup>C-TAGGED POLYACRYLATE POLYMER: COLUMN STUDIES OF FLOW AND RETARDATION IN SAND.** Flow columns filled with sand were used to study migration and retardation of a highly consumer-product, polyacrylate polymer material tagged with <sup>14</sup>C. Five flow column studies of a solution of the polymer demonstrated that a mobile fraction ranging between 32 and 58 percent migrated out of the columns after the passage of up to 50 pore volumes of leachate or distilled water, and most of this occurred well within the first 2 pore volumes. The remainder was highly retarded by the sand near the column inlet. When the polymer was introduced into two other columns as a simulated diaper pad, a much lower migration of 4.6 to 5.6 percent was observed, indicating a blocking phenomenon in the manufactured product form. The effect of typical landfill leachate on the migration and retention of the polymer reduced the migration and enhanced the retardation characteristics of the sand significantly. (Author abstract) 8 refs.

Martin, James E. (Univ of Michigan, Ann Arbor, MI, USA); Howard, Kenneth W.F.; King, Lawrence W. *Nucl Chem Waste Manage* v 7 n 3-4 1987 p 265-271.

**081042 ENVIRONMENTAL BEHAVIOR OF <sup>14</sup>C-TAGGED POLYACRYLATE POLYMER: FLOW TANK STUDIES OF RETENTION IN SAND.** A highly absorbent consumer-product, polyacrylate polymer material tagged with <sup>14</sup>C was dosed to a simulated diaper and buried in a horizontal flow tank containing sand. Two slightly different formulations of the polymer exhibited a mobile fraction, 1.9 percent and 3.48 percent of which was discharged in the tank effluent during the passage of 6 pore volumes. Most of the remainder was retarded along the flow path near the source by the sand. It is expected that more conventional landfill soils would provide even greater retention of the polymer materials studied. The use of a <sup>14</sup>C-tagged polymer proved to be a successful method of studying the behavior of these complex materials; pilot-scale studies are planned in lysimeters to determine if microbial decomposition affects the migration of these polymers under landfill conditions. (Author abstract) 6 refs.

**081043 CARBONIZATION OF POLYACRYLONITRILE IN A TWO-DIMENSIONAL SPACE BETWEEN MONTMORILLONITE LAMELLAE.** A novel method to prepare a new type of carbon from polyacrylonitrile (PAN) was developed by using the interlamellar opening of montmorillonite (MONT) as a two-dimensional space for carbonization. The complex of MONT with PAN was heat treated at 700°C to carbonize the intercalated PAN. The carbon produced was liberated from MONT by acid treatments. The carbon thus obtained looks like thin films under a scanning electron microscope and is considered to consist of planar macromolecules. Although it has a turbostratic structure at 700°C, it becomes a highly oriented graphite upon further heat treatment above 2500°C. An ordinary PAN was also prepared and heat treated for comparison. (Author abstract) 17 refs.

**Chemical Reactions**

**081044 MODIFICATION OF PAN PRECURSOR - ITS INFLUENCE ON THE REACTION KINETICS.** Polyacrylonitrile (PAN) fibers of a special grade for making carbon fibers have been modified by stretching in the presence of a plasticizer to 70% maximum strain. By doing so, the diameter of the original fibers is reduced from 12.5 μ to 10 μ and the angle of orientation of the molecular chains along the fiber axis is reduced to almost half of its original value as determined by the X-ray flat-plate technique. The tensile strength and Young's modulus values of the modified samples show an improvement of about 70% and 100%, respectively. A study on the reaction kinetics up to 265°C by DSC, TGA, and TMA has revealed deviations in the characteristics of modified PAN precursors over those of the original sample. The implications of these are discussed. (Edited author abstract) 33 refs.

**Electronic Properties**

**081046 INFLUENCE OF COPPER-NITRILE COMPLEXING ON THE ELECTRONIC STRUCTURE OF POLYACRYLONITRILE.** The influence of copper-nitrile complexing on the chemical and electronic structure of polyacrylonitrile has been studied by X-ray photoelectron spectroscopy and infrared spectroscopy. The results indicate that the existence of the complex effectively presents the nitrile groups form participating in the thermal cyclization and degradation and reduces the inter(intra)chain dipole-dipole interactions in the polymer, allowing the nitrile chain to become more ordered. This cancels the indirect influence of the dipole field on the polymer backbone. (Author abstract) 38 refs.

**Physical Properties** See SYNTHETIC FIBERS—Applications.

**Pyrolysis**

**081048 STUDY ON THE GASEOUS PRODUCTS OF HIGH TEMPERATURE PYROLYSIS OF ACRYLONITRILE POLYMERS BY ON-LINE FTIR METHOD.** The gaseous products of high temperature pyrolysis (300°C to 960°C) of acrylonitrile polymers were measured continuously under nitrogen atmosphere by on-line Fourier Transform Infrared Spectroscopic (FTIR) method. From the variations of characteristic peaks, it was found that the nitrogen of macromolecules evolved were mainly in the form of hydrogen cyanide and ammonia. During the pyrolysis, an amorphous carbonaceous element was formed and crosslinked to form a network structure. Three kinds of samples were used for comparison. The experimental results show that the gaseous products of volatile small molecules were HCN, NH<sub>3</sub>, CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub> and cyanide. CO and CO<sub>2</sub> were also formed when copolymers of PAN were thermally pyrolyzed. (Author abstract) 10 refs.

**Spectroscopic Analysis**

**081050 INFRARED REFLECTION-ABSORPTION SPECTROSCOPY OF POLYACRYLONITRILE ON**

**COPPER AND ALUMINIUM SURFACES.** Infrared reflection-absorption spectroscopy has been used to study the chemical structure of thin films of pyrolyzed polyacrylonitrile (PAN) on copper and aluminum surfaces. The formation of a conjugated backbone occurs at temperatures as low as 200°C for PAN on copper, whereas the same reaction on aluminum requires pyrolysis at 300°C in order to be completed. Pyrolysis of Pan on copper at 200°C also results in diffusion of copper atoms (ions) into the polymer network followed by complexing. We propose a chemical structure of PAN on copper that is different to that in the bulk and on aluminum. (Edited author abstract) 32 refs.

## Stability

**081051 THERMAL STABILIZATION OF POLY-ACRYLONITRILE FIBERS.** Polyacrylonitrile (PAN) fibers pretreated with potassium permanganate have reduced the activation energy of cyclization and the oxidation time, and also improved the properties of the resultant carbon fibers. The activation energy of cyclization is reduced to  $24 \pm 1$  kcal/mol from  $30 \pm 3$  kcal/mol and the tensile strength of the carbon fibers increases by about 20-40%. The method of measuring the 'aromatization index' (AI) value is modified and is recommended in checking the oxidation process. All fully stabilized PAN fibers have almost the same AI value. However, the oxidation time is decreased by 30 min when oxidation temperature is raised by 10°C. (Author abstract) 31 refs.

## Structure

**081052 PREPARATION OF STARCH GRAFT COPOLYMERS: INFLUENCE OF SEVERAL PARAMETERS ON STRUCTURE AND PROPERTIES.** Samples of starch-g-polyacrylonitrile were prepared using the  $Ce^{4+}$  ion as initiator. We discuss the influence of the origin of the starch on the polyacrylonitrile content of the copolymer, on the frequency of the grafted chains, and on the molecular weight of the graft. Relations between alkaline hydrolysis conditions and liquid absorption were also studied. The retention increases with the molecular weight of the grafted polyacrylonitrile, and this factor depends on the origin of the starch. Higher absorptions were obtained with low amylose content samples. An absorption maximum was observed that depends on the time of hydrolysis and consequently on the carboxylate group content. (Author abstract) 18 refs.

## Wear

**081056 BASIC STUDIES ON THE STABILITY OF FILTRATION FABRICS PART I: THE EFFECTS OF SULPHUR DIOXIDE AND NITROGEN OXIDES ON POLYACRYLONITRILE.** The paper (the first in a series) describes the deterioration of polyacrylonitrile (PAN) fibers under laboratory-simulated conditions by Fourier transform infrared spectroscopy, differential scanning calorimetry, scanning electron microscopy, and tensile strength measurements. The results indicate that the fibers are subject to oxidative degradation (chain scission, formation of  $-CO_2$ ,  $-COOH$ , etc), cyclization via the nitrile side chains, and a slight introduction of  $SO_2$  and  $SO_3$  groups to the polymer chain. All these primary and secondary reactions are basically related to thermal or alkaline degradation of PAN, and both  $SO_2$  and  $NO_2$  appear to play a catalytic role in the oxidation process. (Edited author abstract) 36 Refs.

## POLYAMIDEIMIDES

### Combustion

**081057 ENTHALPIES OF COMBUSTION OF POLYAMIDOIMIDES.** Enthalpies of combustion of polyamidoimides, obtained on the basis of trimellitimido-N-acetic and trimellitimido-N-p-benzoic acid dichlorides and also a series of aromatic diamines, were determined by the combustion method in a calorimetric bomb. A linear dependence of enthalpies of combustion on the relative hydrogen content in the polymer was found. (Author abstract) 5 refs.

Morozova, N.Yu.; Privalko, V.P.; Zamulina, L.I.; Khomenkova, K.K. *Sov Prog Chem* v 53 n 6 1987 p 97-99.

### Curing

**081058 CURING MECHANISM OF POLYAMIDEIMIDE BY HEATING.** Polyamideimide (PAI) samples containing various amounts of amide and imide bonds were prepared by the polycondensation of trimellitic anhydride and trimellitic acid with 4,4'-diphe-

nylmethane diisocyanate. To clarify the curing mechanism of PAI, the effects of heating on its chemical structure and physical properties were investigated. The results suggest that the curing of PAI by heating is due to the crosslinking reaction between functional groups or terminal groups in the main or branch chains. When PAI was heated in air, the oxidation of diphenylmethane structure in the main chain had some influence on the curing of PAI. (Edited author abstract) 14 refs. In Japanese.

## Synthesis

**081059 HIGH MODULUS FIBERS AND FILMS FROM A WHOLLY AROMATIC POLYAMIDE-IMIDE.** Wholly aromatic polyamide-imide fibers and in-plane isotropic films were made from N,N'-bis(2-chloro-4-aminophenyl)terephthalamide and pyromellitic dianhydride. The N-methylpyrrolidone solution of its precursor, poly(amic-acid), was wet-spun into fibers, which were then imidized chemically or thermally. The chemically imidized fiber had tenacity: 12.2 g/d and initial modulus ( $M_i$ ): 1340 g/d. Films were prepared by casting.  $M_i$  of the stiffest film reached 2530 kg/mm<sup>2</sup>. (Edited author abstract) 4 refs. In Japanese.

**081060 POLYMERIZATION OF  $\epsilon$ -CAPROLACTAM IN AN EXTRUDER: PROCESS ANALYSIS AND ASPECTS OF INDUSTRIAL APPLICATION.** The polymerization of caprolactam into polyamide 6 on corotating twin-screw extruders provides the processor with technically and economically interesting aspects of application. Using the extruder as a small reactor, it is possible, on the one hand, for small batches of polyamide to be optimized for specific applications and, on the other hand, for large quantities of polymerized polyamide melts to be fed into different processes. Apart from the extrusion of filaments, films, and profiles, the continuous polymerization process also can be coupled up to discontinuous processes. This so-called rapid polymerization in the extruder not only brings price advantages as compared with standard polyamides, but also gives higher molecular weights and, hence, improved properties. (Author abstract) 16 refs.

## Aging

**081065 PHYSICAL TRANSFORMATIONS AND CHANGE IN MECHANICAL PROPERTIES ON THERMAL AGEING OF ALIPHATIC POLYAMIDES.** In the thermal aging of aliphatic polyamides the density and degree of crystallinity are increased, the supermolecular structure is completed, and microcracks appear in the layers near the surface, which is accompanied by a change in the mechanical properties of the specimens. A change in the angular coefficients of the rate of change of the control criterion as a function of the temperature of thermal aging must be allowed for in selecting the maximum temperature of the tests, which, in the case of aliphatic PA, should not exceed 120°C. The results obtained during thermal aging at temperatures below 120°C can be used in forecasting the time for which the control criterion (properties) can be maintained at a given level. (Edited author abstract). 7 Refs.

**081067 POLYAMIDE (PA).** With a total consumption in the western world of just under 650000 t/a, polyamide (PA) accounts for only about 1% of the total volume of all plastics. With a growth rate of around 6 to 7% this product

group is above the levels of other major plastics types. The old polyamide sector will in the foreseeable future lose none of its vitality. Apart from its balanced range of properties, it is above all the opportunities for variation, as regards the chemical structures, and the diverse possibilities for combination with additives or other polymers. An important aim of product development continues to be the improvement of processing performance and transparency. Amorphous polyamide with high glass transition temperature was developed above all for exterior applications in the automotive sector. In the group of elastomeric polyamides, the development of polyether block amides and thermoplastic polyamide 12 elastomers has enabled further progress. 22 refs.

**081068 RELATIONSHIP BETWEEN ELECTRON SENSITIVITY AND CHEMICAL STRUCTURES OF POLYMERS AS ELECTRON BEAM (EB) RESISTS. V: POLYAMIDES CONTAINING SULFUR GROUPS AS POSITIVE EB RESISTS.** Polyamide-thioethers were synthesized and evaluated as positive electron beam (EB) resists. The polyamidothioethers decomposed easily with EB exposure. At high doses (indicating low sensitivity), crosslinking reactions occurred for polyamidothioethers having C-S bonds produced by Michael addition, but the other polyamidothioethers did not crosslink. The C-S bonds produced by Michael addition may influence crosslinking rather than decomposition. The sensitivity of oxidized polyamidothioether was higher than that of the nonoxidized polymer with no change in resolution. The oxidized polyamidothioether had a higher sensitivity and a high resolution, and is adaptable as a positive EB resist. (Author abstract) 9 refs.

## Chemical Reactions

**081069 REACTIONS OF POLYAMIDES WITH METAL SULFIDES DURING HETEROLYTIC POLYCONDENSATION.** The aim of our investigation was to study the character of the reaction of polyamides with copper and cadmium sulfides, occurring during the preparation of a composite material, by the method of interphase polycondensation in which the syntheses of the polyamide and metal sulfide take place simultaneously at the interface of two immiscible solutions. Using diffuse reflection spectroscopy, it is shown that in the reaction of polyamides with metal sulfides under interphase polycondensation conditions, a coordinational interaction takes place between the carbonyl oxygen atom of the amide group of the polyamide and the metal cation of the sulfide. IR spectroscopic analysis showed that with increase in the degree of cadmium sulfide filling of the polyamide, the number of hydrogen bonds between the carbonyl oxygen atoms and the amide hydrogen atoms decreases, and hydrogen interaction takes place between sulfide sulfur atoms and the hydrogen atoms of the amide and terminal amino groups. 4 refs.

**081070 EFFECT OF CHIRAL GROUP CONCENTRATION ON THE GAS CHROMATOGRAPHIC RESOLUTION BY DIAMIDES [R<sub>1</sub>CONHCH(R<sub>2</sub>)CONHR<sub>3</sub>]. COMPARISON OF LOW-MOLECULAR AND POLYMERIC PHASES.** It has been found that the highest stereoselectivity for N-acyl-α-amino acid esters in GC is observed on polymeric diamide phases if the amounts of bonded selector are relatively low. On the other hand, studies on low-molecular diamides, diluted with achiral aliphatic hydrocarbons, have demonstrated that the stereoselectivity of the diluted diamide molecules is higher than that of the self-associated molecules present in concentrated solution. It was concluded that the

hydrogen bonding between the diamide molecules lowers the importance of the selector-solute interactions responsible for stereoselectivity. In analogy to the low-molecular systems, it is assumed that on the polymer, too, self-association of neighboring diamide moieties distributed along the backbone reduces resolution as the load of the selector becomes higher. ## Corrosion

**081073 STRESS CORROSION CRACKING OF AN IMPACT MODIFIED POLYAMIDE AND ITS SHORT-FIBER COMPOSITES.** An impact modified Polyamide 6.6 (PA6.6) and two short-fiber composites with different loadings of short glass fibers were tested under stress rupture conditions. It was shown that fiber reinforcement can improve the material properties, the effectiveness depending on the fiber orientation, however. A deteriorating influence on the material's strength, especially at longer times of exposure, can be detected in the aggressive environment of a solution of 5% H<sub>2</sub>SO<sub>4</sub> in water. The dependence of the time to final failure on the magnitude of the initial stress intensity factor as well as the rates of crack propagation during loading were measured. Crack advance was monitored by optical microscopy and fractographical studies were performed in the SEM. (Author abstract) 15 refs.

Voss, H. (Technical Univ Hamburg-Harburg, Hamburg, West Ger); Dolgopolsky, A.; Friedrich, K. *Plast Rubber Process Appl* v 8 n 2 1987 p 79-90.

## Crazing

**081074 ENVIRONMENTAL CRAZING IN POLYAMIDES.** Polyamides have been known to stress crack in inorganic salt solutions for two decades but the role and importance of crazing has only been referred to more recently. Illustrated in this letter are various crazes found

in polyamides stressed in certain lithium, magnesium or zinc salt solutions. The primary aim has been to illustrate the morphology of crazes formed in salt-affected polyamides. 21 refs.

## Crystallization

**081075 STIRRING-INDUCED SOLUTION CRYSTALLIZATION OF ULTRA HIGH MOLECULAR WEIGHT POLYAMIDE 6.** Unstable solutions of ultra-high molecular weight polyamide 6 have been prepared by adding a nonsolvent to the polymer solution. Crystallization of the polyamide from such a solution proceeds very slowly. It has been found, however, that vigorous stirring of the unstable solutions induces rapid fibrous crystallization of the polymer. The fiber mat consists of irregularly shaped fibers. A low temperature and a high stirring rate are among the conditions necessary to obtain a high yield of fibrous material. The fibers formed upon stirring have a higher molecular weight than the polyamide 6 molecules which remain in the solution. The melting point of the fibers depends on the speed of the paddle stirrer. (Edited author abstract). 16 Refs.

## Degradation

**081076 THERMAL DEGRADATION OF ALIPHATIC POLYAMIDES STUDIES BY FIELD IONIZATION AND FIELD DESORPTION MASS SPECTROMETRY.** The aliphatic polyamides nylon 6,6, 6,9, 6,10, 6,12, 12,6, 12,10, and 12,12 of the diamine dicarboxylic acid-type were pyrolyzed in the ion source of a double-focusing mass spectrometer and the thermal degradation products were recorded by field ionization (FI) and field desorption (FD) mass spectrometry (MS). In the FI mode, several series of thermal degradation products differing in the number of polymer repeating units were detected up to 1000 Daltons. The main products were oligomers and, in addition, protonated dinitriles and various protonated nitriles are formed in large amounts except for nylon 6,6 and nylon 12,6. These two polymers form, in contrast to all other samples, large amounts of protonated amines and diamines. The technique employed allows distinction between oligomers already present in the original polymer and oligomers formed by thermal fission of bonds in the polymer chain. (Edited author abstract). 11 Refs.

## Dielectric Properties

**081077 DIELECTRIC RELAXATIONS OF POLYAMIDE 12 STUDIED BY THERMALLY STIMULATED CURRENT (TSC) METHOD.** The glass transition temperature of PA 12 of different samples having different molecular masses has been studied by the thermally stimulated current method. The relaxation  $\beta$  observed between 43°C and 53°C for different molecular masses and a critical mass of 4000 for PA 12 has been found. The thin structure of  $\beta$  for the sample having molecular mass of 12000 has been analyzed. Maximum energy observed is 2.52 eV at 54°C. The relaxation times corresponding to the first ten elementary peaks obtained by the fractional polarization method obey a compensation law with  $T_c = 357K$  and  $\tau_c = 7.8 \times 10^{-3}s$ . (Author abstract) 17 refs.

Faruque, Hafiz S. (Univ Paul Sabatier, Toulouse, Fr); Lacabanne, C. *Indian J Pure Appl Phys* v 25 n 3 Mar 1987 p 114-117.

## Fillers

**081078 INFLUENCE OF THE INTERACTION OF POLYMERS WITH FILLERS ON THE PARAMETERS OF MECHANOEMISSION.** A correlation between the parameters of the emission of high-energy electrons and the degree of interaction between polymers and mineral fillers in composite materials has been established. It is found that when the polymer interacts with a filler, the number of functional groups responsible for adhesion decreases, since they are coordinated by chromium. The amplitude of the emission flux consequently decreases as a result of the decrease in the number of contacting functional groups per unit of area. Therefore, the nature of the functional groups and their concentration on the surface has a significant influence on the emission parameters. An analysis of the results obtained allows us to conclude that the emission parameters are sensitive characteristics of the structural changes in filled systems and that the emission of high-energy electrons can be employed as a method of nondestructive testing for evaluating the changes in the properties of the surface of a material during service. (Edited author abstract) 5 refs.

## Film

**081079 SEPARATION OF H<sub>2</sub> AND CO THROUGH POLY(SULFONE-AMIDE) MEMBRANES. II. HIGHLY PERMESELECTIVE MEMBRANES CONTAINING BIS(3-AMINOPHENYL)SULFONE AS A DIAMINE COMPONENT.** The authors have studied hydrogen separation membranes made from aromatic polyamides containing sulfone linkages in the main chain. This paper reports the permeation behavior of H<sub>2</sub> and CO through the poly(sulfone-amide) containing bis(3-aminophenyl)sulfone (3DDS) as a main diamine component. 3DDS has no ether linkage, so the poly(sulfone-amide) comprising 3DDS has a higher concentration of amide linkages in the main chain than the poly(sulfone-amide) comprising 4SED has. Moreover, the amino group of 3DDS is bonded on the m-position. This structure introduces a bent structure in the polymer chain. These effects are expected to contribute to high permselectivity. 7 Refs.

## Friction

**081080 SOME TRIBOTECHNICAL CHARACTERISTICS OF POLYAMIDE FACINGS ADHESIVELY BONDED WITH A POROUS METAL MATRIX.** We study the effectiveness under conditions of rolling friction with slip of polyamide 6 (PA6) facings of thickness 0.5-2.5 mm, adhesively bonded with the aid of mark PFE 2/10 methylolpolyamide with porous reinforcing elements (RE) of sintered iron powder. Use of the facings makes it possible to improve the load capacity by 10-80% in comparison with monolithic PA6 specimens. We conclude that it is necessary to develop special adhesives for impregnation of the porous RE, capable of forming with the facing material an adhesive bond that is resistant to the action of dynamic contact loads. (Author abstract) 8 refs.

## Grafting See Also PULP—Grafting.

**081081 GRAFTING OF PREFORMED POLYAMIDE ONTO CELLULOSE ACETATE.** With few exceptions, grafting of synthetic polymers onto cellulose and cellulose derivatives is carried out by mechanisms involving free radical addition. These methods give large amounts of ungrafted homopolymer, little control over the molecular weight and molecular weight distribution of the grafted polymer, and other problems. By introducing

methanesulfonyl (mesyl) groups on cellulose acetate, we have found that preformed polyamide with free carboxylate end groups will displace the mesyl group and form an ester linkage in a homogeneous phase reaction. Grafting yield is over 80 percent after reaction at 80°C for 20 hours. (Author abstract) 6 refs.

## High Temperature Effects

**081082 THERMAL EXPANSION OF THE CRYSTALLINE LATTICE OF POLYAMIDES.** X-ray structural analysis is used to study the thermodynamics of the crystalline lattice of isotropic polyamide samples: polyhexamethylenedipamide, polycapromide, polyhexamethylenesbacinamide and polydodecanamide. It is shown that change in the parameters of the lattice with rise in temperature is of a non-linear character. Break points in the dilatometric curves are observed at 100-120 and 180-200°C. In the first temperature region heavy rupture of the hydrogen bonds in the crystalline lattice begins with phase transition in the second to the hexagonal structure. (Author abstract). 14 Refs.

Kazaryan, L.G. (Plastmassy Science-Production Assoc, USSR); Zezina, L.A.; Pavlov, N.N. *Polym Sci USSR* v 29 n 5 1987 p 1052-1058.

## Hydrolysis

**081083 HYDROLYSIS AND OTHER PHENOMENA AFFECTING STRUCTURE AND PERFORMANCE OF POLYAMIDE 6 MEMBRANE.** The rate of hydrolysis of polyamide 6 in membrane casting solution containing strong mineral acid has been studied by determining changes in molecular weight, as estimated from dilute solution viscometry measurements. Hydrolysis is shown to be first order with a long half-life of about 250 days. A two-step dissolution process for polyamide 6 is proposed. The effect of extended dope maturation time upon polyamide 6 membrane preparation and performance has been examined. At short maturation times where protonation of polymer chain is occurring, flux is relatively low. A major increase in flux occurs after about 10 h, when protonation appears complete and hydrolysis has begun. Hydrolysis reduces polymer chain entanglement, and so quite different mechanisms for membrane formation exist as dope maturation time proceeds. With chains less than the critical entanglement length, nodular top layer membranes and alveolar walls lead to high water flux. However, such membranes are quite fragile. (Author abstract) 20 refs.

**081085 IMPACT-RESISTANT POLYAMIDE ALLOYS: STRUCTURE AND PROPERTIES OF IM-**

**PACT MODIFIED PA 6 AND PA 66 COMPARED WITH UNMODIFIED HOMOPOLYMERS.** This paper covers the modification of polyamides to make them impact resistant. Some of the topics discussed include the marketing and conditioning costs of polyamides. Other topics covered are used of polyolefin particles as property modifiers; polyamides as multiphase systems; and mechanical and physical properties of the modified polyamides. In English and German.

Lohe, P.; Arndt, J. *Kunstst Ger Plast* v 78 n 1 Jan 1988 p 15-17.

**081086 SEGMENTAL DYNAMICS IN NYLON 66.** The authors present a preliminary account of the characterization of segmental dynamics of specifically deuterated nylon 66 polymers (polyhexamethylene adipamide) that allow us to individually identify the molecular motion that each methylene unit undergoes and thus to examine questions as to the cooperativity of motion. Furthermore, this system has the advantage of allowing us to separately examine subsystems of five and seven bonds which are nominally pinned by the hydrogen-bonding amide sites. Preliminary results for each of the methylene groups in the crystalline domains indicate that there is considerable internal rotational freedom as well as librational motion well below the melting point and the motion of all five methylene groups is quite similar at all temperatures above the Brill transition. 10 refs.

**Oxidation**

**081090 NONINHIBITED AND INHIBITED OXIDATION OF POLYAMIDES.** Oxidation of polyamide-6,6 (PA-6,6) has been investigated at 150-230°C at various oxygen pressure. The oxidation reaction involves only a small fraction of the polymeric material containing 0.6 percent methylene groups at 155°, and 1.4 percent at 200°, percentages that are not a function of the O<sub>2</sub> pressure. The PA-6,6 hydroperoxide contains not less than two fractions that are quite dissimilar as to their stability. Features of oxidation of the polymer are in good agreement with a zone model of the process. According to this model the oxidation process primarily involves zones of disruption of short-range order existing in the polymer. (Author abstract). 5 Refs.

**081091 PREPARATION AND PROPERTIES OF SILICON CONTAINING COPOLYAMIDES.** Copolyamides containing siloxane moieties in main chain were prepared by a melt polycondensation with 1,3-bis(3-aminopropyl)tetramethyldisiloxane (E), hexamethylenediamine (N6), and adipic acid (6). Glass transition temperature (T<sub>g</sub>), cold crystallization temperature (T<sub>cc</sub>), and melting temperature (T<sub>m</sub>) were measured by differential thermal analysis (DTA). The depression of T<sub>m</sub> for copolyamide was fitted by the Flory curve. These DTA studies suggest that the crystallization of N66 component in copolyamide is hindered by the bulky siloxane moiety, while the micro-Brownian motion of amorphous segment is promoted by the flexible siloxane bond. (Edited author abstract) 16 refs.

**081092 POLYELECTROLYTE SWELLING OF POLYAMIDOBENZIMIDAZOLE.** The extreme character of swelling of PABI fibers in DMAc-water mixtures has been detected. The swelling maximum is at an alkali content of 10-12% in water. The maximum is observed in the region of a 10% water content. The peculiarity in swelling has been explained by the manifestation of a polyelectrolyte nature of the polymer. 6 refs.

**081093 DEFORMATION OF A JET OF AROMATIC POLYAMIDE SPUN BY THE DRY-WET METHOD.** The distribution of jet velocities in the air gap and of the degree of stretching between the liquid (in the air gap) and gel-form sections of the fibers being spun from solutions of an aromatic heterocyclic polyamide by

the dry-wet method has been examined. It has been shown that the distribution of jet velocities in the air gap depends on the spinneret hole diameter, the molecular weight of the polymer, and the rate of yarn take-up on the take-up device. Conditions for lengthwise shrinkage of the gel-form fiber in the precipitation bath have been determined. 2 refs.

**081094 LINEAR A-B AND AA-BB POLYAMIDES WITH BACKBONE ARYL, ALKYL, AND ALKENYL UNITS.** High performance linear AA-BB and A-B polyamides were generated using polymerization schemes that gave polymers in higher yields and having better performance than previous methods. Polymers were characterized with FTIR, solution and solid-state <sup>13</sup>C-NMR and showed the incorporation of aryl, alkyl, and alkenyl linkages in the polymer backbone. Thermal analysis showed that a significant weight percent of the polymers remained at 1000°C. (Author abstract). 17 Refs.

**Solutions**

**081097 WATER INSOLUBLE POLYACRYLAMIDE PART VI: DILUTE SOLUTION PROPERTIES OF POLY(N-ACRYLOYL-m-AMINO BENZOIC ACID).** A high molecular weight poly(N-acryloyl-m-aminobenzoic acid) (PMAB) was synthesized in a mixed solvent medium by radical polymerization. The polymer was separated into different fractions by fractional precipitation. All those eight fractions were characterized by viscometry, vapor pressure osmometry and gel permeation chromatography. Mark-Houwink-Kuhn-Sakurada relationships were established for three different solvents at 30°C. Unperturbed dimensions were estimated from the viscosity-molecular weight data using graphical methods based on approximate theories of Stockmayer

and Fixman, and of Kurata, Stockmayer, and Roig, and on a first-order perturbation treatment of the excluded volume effect. The results indicate that the PMAB chain is of intermediate stiffness. (Author abstract) 24 refs.

**081099 STRUCTURAL INVESTIGATION OF POLYAMIDE-6 AND POLYAMIDE-6 COMPOSITES USING <sup>13</sup>C CROSS POLARIZATION/MAGIC ANGLE SPINNING NMR.** Natural-abundance <sup>13</sup>C NMR spectra of pure polyamide-6 (PA6) and polyamide-6 composites were measured with CP and MAS techniques. The microcomposites were made by adding glass microspheres, a silane coupling agent, or prefunctionalized glass spheres to PA6. <sup>13</sup>C NMR spectra of these samples show the presence of three components: two crystalline phases and an amorphous component. The chemical shifts of both carbons adjacent to the amide group are sensitive to the PA6 crystal structure; in the dominant  $\alpha$  polymorph, C1 and C5 are 3 ppm downfield from their chemical shift values in the  $\gamma$  polymorph. Both the X-ray diffraction powder patterns and the <sup>13</sup>C NMR spectra show a change in the relative amounts of the two crystalline components when the composites are made. **081100 STUDIUL PRIN SPECTROMETRIE IN IR AL COMPORTARIIL FIBRELOR DIN POLIAMIDA-6 LA TRATAMENT TERMIC.** [Study of the Behavior of Thermally Treated Polyamide-6 Fibers by IR Spectroscopy]. The paper proposes the study by IR spectroscopy of the crystalline characteristics of some polyamide-6-fibers, thermally treated at temperatures in the range between 180 and 220°C. In order to show the influence of the modification of a physical-chemical parameter on a physical-mechanical characteristic (tensile strength) at thermal treatment, measurements of the tensile strength were done and were correlated to the crystalline characteristics. Thus, the temperature of 210°C is defined as a temperature which modifies crystalline structure of the polymer. (Edited author abstract). 12 Refs. In Romanian.

**081101 STRUCTURE AND PROPERTIES OF SEGMENTED POLYAMIDES.** Segmented polyamides composed of polyether and polyamide structural units are industrially very interesting thermoplastic materials of construction, having a broad spectrum of properties. The

principal reason for this broad spectrum is the polyphase structure of the materials and the possibility of influencing this structure by choice of the ratio of oligoether to oligoamide as well as choice of the mean block lengths. In general, three phases can be detected. In addition, at relatively high oligoether contents, a crystalline oligoether phase is at times encountered to a minor degree. **081102 ORIENTATION OF MOLECULAR GROUPS IN CROSS SECTION OF POLYAMIDE-6 FIBER BY INFRARED ATTENUATED TOTAL REFLECTION DICHOISM STUDIES.** The polymer fiber usually possesses typical uniaxial orientation. The molecular chains are symmetrically distributed around the fiber axis. In this work, the orientation of molecular groups in the cross section of polyamide-6 fiber has been measured by using the IR ATR method. The results indicated that the polyamide-6 fiber mainly contains  $\alpha$ -crystalline form. The direction of hydrogen bonds of amide groups is predominately parallel with the surface in the cross section of the fiber. (Author abstract) 10 refs.

## Swelling

**081103 SWELLING OF AROMATIC POLYAMIDE FIBRES IN ACTIVE MEDIA.** It was of interest to examine the possibility of using the well-known method of fiber swelling in active media to evaluate the structural features of aromatic polyamide fibers, including the state of the surface skin. This article is devoted to an examination of this question. The authors selected two copolymeric amide fibers, differing in the proportion of imidazole and p-phenylene rings (PABI and PABI-S). It is found that for heat-stretched PABI fibers, the swelling picture does not change fundamentally, however, the rate and degree of shrinkage are significantly greater. It is suggested that this is connected with the fact that additional stresses appear in heat-stretching, plus defects, and breaks in continuity which involve mainly the interfibrillar regions and are not propagated into the depths of the fibrils. 1 ref.

**081104 SYNTHESIS OF SOME NOVEL POLYAMIDES.** Among various high-temperature organic polymers, the aromatic polyamides have shown excellent thermal stability due to the stiffness of the polymer chain and hydrogen bonding of the amide groups, but had limited solubility in most organic solvents. With this in mind, an attempt has been made to synthesize aromatic polyamides with good thermal stability and better solubility in organic solvents. Their comparative thermal stability, inherent viscosity, solubility, etc., have been determined. (Author abstract) 7 refs.

**081107 HYDROGEN TRANSFER POLYMERIZATION OF ACRYLAMIDE DERIVATIVES BY SODIUM NAPHTHALENE.** The hydrogen transfer polymerization of crotonamide (CAm) and tiglinamide (TAm) catalyzed by sodium naphthalene was studied under various conditions. Pyridine, xylene and chlorobenzene served as good solvents in the polymerization of CAm, whereas, non-polar solvents such as xylene and toluene in the polymerization of TAm. The reaction products were mainly poly-( $\beta$ -amino acids) in all systems. The hydrogen transfer polymerization rates of CAm, TAm, acrylamide (AAm) and methacrylamide (MAAm) in pyridine were in the following order: AAm > CAm > MAAM > TAm > . The polymerization of N-substituted acrylamides and their derivatives were also investigated. (Edited author abstract) 15 refs. In Japanese.

**081108 PREPARATION OF PROPERTIES OF POLYAMIDES FROM 4-PHENOXY- AND 4-PHENYLTHIO-m-PHENYLENEDIAMINE AND BOTH AROMATIC AND ALIPHATIC DIACIDS.** New soluble aramids having pendant phenoxy and phenylthio groups were prepared in high molecular weights by the polycondensation of aromatic diacids with 4-phenoxy-m-phenylenediamine and 4-phenylthio-m-phenylenediamine, respectively. Glass transition temperatures (T<sub>g</sub>) of these aramids were in the range 195-255°C, where T<sub>g</sub>s of phenoxy pendant aramids were higher than those of phenylthio substituted aramids. These properties were compared with those of the parent aramids derived from m-phenylenediamine and aromatic diacids. Aromatic-aliphatic polyamides were also prepared by the reaction of these three diamines with aliphatic diacids having 4-10 methylene groups and were characterized in detail. (Author abstract) 13 refs.

**081109 SYNTHESIS AND PROPERTIES OF POLYAMIDES DERIVED FROM SYSTEMATICALLY HALOGENATED TEREPHTHALIC ACIDS WITH FLUORINE, CHLORINE, OR BROMINE ATOMS.** Aromatic polyamides were prepared from systematically halogenated terephthalic acids with hexamethylene diamine, piperazine, 4,4'-diaminodiphenylether and p-phenylene diamine by interfacial or low temperature solution polycondensation. The halogenated terephthalic acids used have mono-, di-, or tetra-substituted fluorine, chlorine, or bromine atoms on the benzene ring. The nonhalogenated terephthalic acid was also used for the comparison. The effects of halogen substitution on the benzene ring on the synthesis and some properties of polymers were examined. The flame-retardancy estimated by thermogravimetry, self-ignition, and flash-ignition test

increased with increasing halogen content of the polymers. Solubility increased remarkably by halogen substitution. (Edited author abstract) 25 refs.

**081110 NYLON 6,6 COPOLYAMIDES OF BIS(2-CARBOXYETHYL)METHYLPHOSPHINE OXIDE.** Copolyamides of nylon 6,6 with bis(2-carboxyethyl)methylphosphine oxide (CEMPO) were prepared by melt polycondensation of nylon 6,6 salt with CEMPO and hexamethylene diamine. The effect of CEMPO upon melting point, moisture regain, boiling water shrinkage, water wicking, tensile properties, thermal stability, static dissipation, and flammability of nylon 6,6 fibers and fabrics was determined. The fiber properties were greatly affected by the high water absorption and solubility characteristics of the phosphine oxide linkage. The copolyamides were of improved flame resistance compared to nylon 6,6 and were also found to give improved flame resistance in blends of the copolymer with various commercial plastics. (Edited author abstract) 14 refs.

**081112 DIPHENYL (2,3-DIHYDRO-2-THIOXO-3-BENZOXAZOLYL)PHOSPHONATE: A NEW, REACTIVE ACTIVATING AGENT FOR THE SYNTHESIS OF AMIDES AND POLYAMIDES.** A new activating agent for amide condensations, diphenyl (2,3-dihydro-2-thioxo-3-benzoxazolyl)phosphonate (1), was readily prepared at room temperature by the reaction of 2-benzoxazolethiol (3) with diphenyl phosphorochloridate (2) in the presence of triethylamine (TEA) in benzene. The reaction of carboxylic acids with amines in the presence of 1 was investigated by two procedures, a two-step and a one-step procedure. Both procedures gave corresponding amides in high yields under mild conditions. The direct polycondensation of dicarboxylic acids with diamines by using the activating agent 1 in the presence of TEA proceeded smoothly at room temperature to produce polyamides with inherent viscosities up to 1.2 dL g<sup>-1</sup>. (Edited author abstract) 8 refs.

**081113 ZIGZAG POLYAMIDES COMPRISING RODLIKE SEGMENTS CONNECTED BY FREELY ROTATING OR STIFF JOINTS.** Six fully aromatic zigzag polyamides were synthesized and characterized. The angles between their rigid rodlike segments are all fixed at 119° and 120°. Three of the polyamides have joints between the rodlike segments with free torsional rotation, and three have rather stiff joints. In solution and the amorphous bulk they all adopt a random coil configuration. The behavior of all polymers in dilute solution is dictated by their equilibrium rigidity, with no significant difference between those having freely rotating joints and those having stiff joints. With increased concentration

effects of kinetic rigidity become more prominent because the slowness or rapidity of torsional motion interferes in varying degrees with the free movement of interpenetrated coils and their segments. Two groups of radii of gyration were measured in dilute solution for all polymers. (Edited author abstract) 40 refs.

Aharoni, Shaul M. (Allied-Signal Corp, Morristown, NJ, USA). *Macromolecules* v 21 n 1 Jan 1988 p 185-194.

**081114 POLYAMIDES BASED ON DDT DERIVATIVES.** The authors used two DDT derivatives to synthesize soluble and flame-resistant polyamides. The monomers were obtained by sequential nitration, dehydrochlorination and reduction of DDT derivatives. The polyamides were synthesized by low-temperature polycondensation of these monomers, with dichloroanhydrides of isophthalic and terephthalic acids. Their oxygen index was equal to 55.6-59.9 which proves the high flame resistance of the chlorine containing polyamides. The solubility of the synthesized products in organic solvents was several times higher than that of regular polyamides. In Russian. 13 refs.

**081115 SYNTHESIS OF AROMATIC POLYAMIDES FROM N,N'-BIS(TRIMETHYLSILYL)-SUBSTITUTED AROMATIC DIAMINES AND AROMATIC DIACID CHLORIDES.** A novel and facile method for the synthesis of high molecular weight aramids has been developed by the use of N,N'-bis(trimethylsilyl)-substituted aromatic diamines which were found to be more reactive toward aromatic diacid chlorides than the parent unsubstituted diamines. The low-temperature solution polycondensation of the N-silylated aromatic diamines with aromatic diacid chlorides afforded readily a series of aramids having inherent viscosities of 2.4-7.4 dL g<sup>-1</sup> with the elimination of trimethylsilyl chloride under neutral and milder reaction conditions, compared with the conventional diamine-diacid chloride method. (Author abstract) 15 refs.

Oishi, Yoshiyuki (Tokyo Inst of Technology, Tokyo, Jpn); Kakimoto, Masa-aki; Imai, Yoshio. *Macromolecules* v 21 n 3 Mar 1988 p 547-550.

**081116 NOVEL PHENYL-SUBSTITUTED AROMATIC POLYAMIDES.** Based on previous experimental work the authors assumed that a phenyl substituent will be effective in increasing the solubility of rigid-rod aromatic polyamides, and two types of aromatic polyamides were prepared which will be described briefly. It is shown that the phenyl substituent not only makes the aromatic polyamides more soluble, it also depresses the melting temperature. To our knowledge, this is the first report which discloses melting transitions for wholly aromatic para-linked polyamides without substitution on nitrogen. 15 refs.

**081117 ACYLLACTAM-TYPE GROWABLE END GROUP FORMED IN THE ANIONIC POLYMERIZATION OF A BICYCLIC OXALACTAM. THE ISOLATION OF THE POLYAMIDE AND ITS USE AS AN ACTIVATOR IN THE POLYMERIZATION OF 2-PYRROLIDONE.** A bicyclic oxalactam, 8-oxa-6-azabicyclo[3.2.1]octan-7-one was anionically polymerized in dimethyl sulfoxide at room temperature and the resulting hydrophilic polyamide having an acyllactam-type growable chain end was isolated from the polymerization system. The reactive end group was found to be easily converted to other functional groups by the hydrolysis or aminolysis by suppressing the simultaneous decomposition of the polyamide chain. The terminal acyllactam group in the polyamide, which was used as an activator in the anionic polymerization of 2-pyrrolidone, was quantitatively consumed and all of the macromolecular activator could be incorporated into the resulting

copolymer. The thermal behavior and crystallization of the AB-type block copolymers composed of the hydrophilic polyamide and nylon-4 segments were influenced by the characteristics of the hydrophilic polyamide segment. (Author abstract) 21 refs.

Hashimoto, Kazuhiko (Nagoya Univ, Nagoya, Jpn); Sumitomo, Hiroshi; Shinoda, Housei. *Polym J* v 20 n 4 1988 p 321-331.

**081118 CYCLOPOLYMERIZATION OF N-ALKYL-N-ALLYLACRYLAMIDES.** Free-radical polymerization of N-alkyl-N-allylacrylamides, where N-alkyl substituents were N-methyl, N-butyl, and N-octyl, was carried out with  $\alpha,\alpha'$ -azobisisobutyronitrile (AIBN) at 60°C. Soluble polymers were prepared when the extent of conversion was low or even high in the polymerization with low monomer concentration. Residual carbon-carbon double bonds in the polymers were determined by both spectroscopic and titrimetric methods to be only allyl groups. The degree of cyclization increased either with decrease in the monomer concentration or increase in the chain length of N-alkyl groups. A suggested mechanism of cyclopolymerization is discussed. Copolymerization of mono-olefins having each counterpart of dienes was also carried out to give the copolymers containing mainly the acryloyl monomers. (Edited author abstract) 12 refs.

**081120 POLYAMIDE SYNTHESIS BY DIRECT POLYCONDENSATION WITH PHENYLPHOSPHONIC DICHLORIDE IN PYRIDINE.** The direct polycondensation of isophthalic acid (IPA) and aromatic diamines with a new phosphorus compound, phenylphosphonic dichloride (PPDC), was studied. PPDC could actually react with nearly a two molar amount of carboxyl groups, but more than 75 mol percent PPDC with respect to the carboxyl groups of IPA were satisfactorily used in the polycondensation. The initial reaction of IPA with PPDC in pyridine at room temperature and then at 120°C was needed to complete the activation, and the subsequent aminolysis at 120°C for 3 h was most effective. The polyamides of high inherent viscosity were obtained even from weakly basic aromatic diamines, and their values were more than those obtained by the conventional method. (Edited author abstract) 9 Refs.

Kigashi, Fukuji (Tokyo Univ of Agriculture & Technology, Koganei, Jpn); Lee, Yen-Nehg; Kobayashi, Akira. *J Polym Sci Part A* v 26 n 8 Aug 5 1988 p 2077-2083.

**081121 SYNTHESIS OF POLYAMIDES BASED ON 1,8-DIAMINO-P-METHANE.** The synthesis of polymeric materials from relatively inexpensive renewable resources has assumed increased importance in recent years. In this vein it would seem, from the standpoint of cost and availability, that limonene and its derivatives should be among the most promising of raw materials for resin and/or polymer synthesis. However, a survey of the

literature revealed that while some use is made of limonene itself, little use is made of its derivatives as starting materials for resin or polymer synthesis. The authors investigated the synthesis of polymers from a readily available limonene derivative, 1,8-diamino-p-menthane (DAM). The present communication concerns the synthesis of polyamides from this diamine and various acid chlorides. 9 Refs.

Trumbo, D.L. (Glidden Co, Strongsville, OH, USA). *J Polym Sci Part C* v 26 n 9 Aug 20 1988 p 405-408.

**081122 SYNTHESIS OF POLYAMIDES BY DIRECT POLYCONDENSATION WITH PROPYLPHOSPHONIC ANHYDRIDE AS AN ACTIVATING AGENT.** A 50 wt% solution of propylphosphonic anhydride in NMP as an activating agent was used for the synthesis of amides from carboxylic acids and amines. The direct polycondensation of dicarboxylic acids with aromatic diamines using the activating agent in the presence of pyridine proceeded at 100°C to produce polyamides with inherent viscosities up to 1.6 dl g<sup>-1</sup>. Furthermore, the activating agent was used for the chemoselective polyamidation; that is, polyamides from dicarboxylic acids and diamines containing various functional groups were prepared without special protection of the acylation-sensitive groups. (Author abstract). 5 Refs.

## Thermal Properties

**081123 CHANGES OF THE THERMAL CHARACTERISTICS OF POLYAMIDES DURING FILLING WITH METAL SILICATES BY INTERPHASE POLYCONDENSATION.** The authors studied the character of variation of the softening point  $T_{\text{soft}}$  of polyhexamethylenedipamide (PHMAA) and of the melting and decomposition points ( $T_m$  and  $T_{\text{dec}}$ ) of polyhexamethylenesbacamide (PHMSA) filled with copper and magnesium silicates by interphase polycondensation. It is shown that when polyamides are filled with metal silicates by the interphase polycondensation method polyamides of high molecular weight are formed at filler contents below 1.5-2.0 mass %, while at filler contents above 1.5%-2.0 mass % the molecular weight of the resultant polyamide falls sharply. It is also shown that during production of polyamides filled with silicates by the interphase polycondensation method their thermal characteristics may be raised or lowered by variation of the filler content. 5 refs.

## Thermodynamics

**081124 THERMODYNAMICS OF AROMATIC POLYAMIDES, SYNTHESIS PROCESSES AND STARTING SUBSTANCES REVIEW.** The changes in the enthalpy, entropy and Gibbs function have been determined and the equilibrium constants calculated for 18 reactions of polycondensation of isomeric phenylene diamines with iso and terephthalic acids and their derivatives at 101.325 kPa and 50-400 K. The influence of the structure of the diamines molecules and also the nature of the substituent in the molecule of electrophilic reagent on the thermodynamic functions of the reactions of polyamidation has been characterized. Series of standard changes in the Gibbs function are compiled and it is shown that combination of the starting substances leads to wide variation in the equilibrium constant of the polyamidization reactions. (Author abstract). 16 Refs.

## Viscosity

**081125 ON THE VISCOSITY PROPERTIES AND THE PHASE STABILITY OF ALIPHATIC POLYAMIDES IN VARIOUS SOLVENTS.** The viscosity

properties of aliphatic polyamides (polycapraamide and polydodecanamide) in various solvents have been investigated. Viscosity vs. concentration curves have been plotted for each of the polyamide-solvent systems. On the basis of the temperature dependence of viscosity for solutions of various concentrations, and using the interferometric data the points of phase transitions have been determined, and the phase diagrams constructed. (Author abstract) 9 refs.

## Welding

**081126 INJECTION WELDING OF POLYAMIDES.** In this paper, the authors discuss welding of polyamides inside the injection mold. This process is called injection welding. The process of injection welding makes it possible to bond polyamides with quite different characteristics together without adhesive. In this way, one can achieve economic as well as constructional advantages. Two different methods are discussed. The weld line strengths of injection-welded parts depend on material and process conditions. (Edited author abstract)

## POLYBUTADIENES See Also LACQUER AND LACQUERING; POLYURETHANES—Structure.

**081127 PHOTOELASTIC PROPERTIES OF POLYBUTADIENE RUBBERS.** Two polybutadiene polymers were used in this investigation, one with 98% cis-1,4 units and the other with an approximately equibinary mixture of cis and trans units. A range of cross-linking densities were obtained using dicumyl peroxide as a vulcanizing agent. The experiments involved measurement of both the elastic force and birefringence (using the changes in length at constant temperature) over the temperature range -10-20°C. The force-extension curves for both rubbers were similar in form. Both showed a strong upward deviation from the Gaussian statistical theory at high extensions, especially at lower temperature in which the extension to break increases. Both polymers showed the stress-optical coefficient to be substantially independent of the degree of cross-linking. (Edited author abstract) 26 refs.

**081128 NOVEL DETERMINATION OF 1,4-POLYBUTADIENE ISOMERS BY USE OF J-COUPLED CONSTANT BETWEEN TWO OLEFINIC PROTONS.** In this paper, the authors attempted to observe the <sup>13</sup>C satellite signals of the olefinic protons of trans- and cis-1,4-polybutadienes in order to obtain the coupling constant between methine protons. They distinguished between cis- and trans-isomers on the basis of observed coupling constants. 2 refs.

## Adhesion

**081129 CATHODIC DELAMINATION OF POLYBUTADIENE FROM STEEL.** The variables influencing the rate of the cathodic delamination of polybutadiene from steel in alkali halide solutions are discussed. The bond at the interface arises from the reaction of carboxyl groups in the polybutadiene with hydroxyl groups on the surface of the iron oxide at the interface. It is this bond that is broken by hydroxyl ions generated by the oxygen reduction reaction beneath the coating. The rate controlling step is the rate of charge transfer through the coating to support the oxygen reduction reaction. (Author abstract) 32 refs.

Leidheiser, Henry Jr. (Lehigh Univ, Bethlehem, PA,

USA). *J Adhes Sci Technol* v 1 n 1 1987 p 79-98.

## Adsorption

**081130 ADSORPTION OF POLYBUTADIENES WITH POLAR GROUP TERMINATIONS ON THE SOLID SURFACE. 1. INFRARED STUDY AT THE SILICA SURFACE.** Adsorption of polybutadiene terminated with a very polar functional group (T-PBR) on a silica surface from carbon tetrachloride solution has been investigated by using IR spectroscopy and compared with normal polybutadienes (PBR). Carbon tetrachloride is a good solvent for polybutadiene. The adsorbed amount,  $A$ , the surface coverage  $\theta$  of the silanol groups, and the bound fraction of a polymer chain  $p$  were observed. T-PBR has an  $A$  and  $\theta$  twice as large as those for PBR, while the  $p$  value was approximately the same for both polymers. (Edited author abstract) 24 refs.

## Aging

**081131 INFLUENCE OF AGEING ON STRENGTH PROPERTIES AND MORPHOLOGY OF FRACTURE SURFACE OF HYDROXY TERMINATED POLYBUTADIENE RUBBER.** Vulcanizates of hydroxy-terminated polybutadiene (HPB) rubber having a range of crosslinking density have been prepared by varying the amount of curing agent, toluene-di-isocyanate (TDI). The effect of oxidative aging of these rubbers on the tensile and tear strength has been investigated. Kinetic of aging of the samples are also reported. The tensile strength, tear strength, modulus and hardness increase with the increase in the amount of TDI i.e. crosslinks. In general, there is an initial drop in the tensile strength and tear strength of these rubbers with time or temperature of aging. There is a stiffening effect afterwards, particularly for HPB rubbers cured with a lower amount of TDI. (Edited author abstract) 15 refs.

## Applications See EXPLOSIVES—Efficiency.

## Blending See POLYSTYRENES—Blending.

## Crosslinking

**081132 VISCOELASTIC DISSIPATION AND THE TEAR ENERGY OF URETHANE-CROSS-LINKED POLYBUTADIENE ELASTOMERS.** A series of urethane-cross-linked polybutadiene elastomers of varying cross-linking levels have been investigated to determine the relationship between viscoelastic dissipation and tear (or fracture) resistance. Several points of correspondence were identified between these two properties. The first was an inverse proportionality in the terminal region between cross-link density and torsional creep behavior as well as tear energy data, with the looser networks being more dissipative and displaying the greatest resistance to tear. Second, master curves of both creep compliance and tear energy exhibited an intermediate plateau. This plateau measured approximately 13 decades in time. The temperature dependences were the same for the tear energy and creep compliance. In the terminal or long time region, the dynamic loss modulus  $G''$  could be linearly correlated with the tear energy. (Author abstract) 36 refs.

## Crystallization

**081133 CHAIN ENTANGLEMENT AND CRYSTALLIZATION OF cis-1,4-POLYBUTADIENE.** The morphological structure and mechanism of nucleation and growth of Ln-PB and Ni-PB with different molecular

weight were investigated by transmission electron microscopy. The crystallization of low molecular weight fraction is primarily from predetermined nuclei, crystallization for the high molecular weight fraction is primarily from sporadic nuclei. Two types of morphology of spherulite with different lamellar entanglement have been observed. The entanglement of higher molecular weight fractions are found to be of significance in the morphology and rate of crystallization of polymer. (Edited author abstract) 3 refs.

Zhou, Enle (Acad Sinica, Changchun, China); Jin, Guiping; Zhang, Yenshou. *Chin J Polym Sci (Engl Ed)* v 4 n 3 Jan 1987 p 207-213.

**081134 STUDY OF LOW-TEMPERATURE CRYSTALLIZATION BEHAVIOR: THE CIS-1,4 POLYBUTADIENE PREPARED WITH RARE-EARTH CATALYST SYSTEM.** The effects of molecular weight and temperature on crystallization processes at low temperature for cis-1,4 polybutadiene prepared with rare-earth catalyst (Ln-PB) have been studied by WAXD method. In the range of molecular weight from  $\langle M_n \rangle = 2.13 \times 10^5$  to  $46.8 \times 10^5$ , there are a maximum of crystallization rate at  $\langle M_n \rangle \approx 29 \times 10^5$  and a minimum at  $\langle M_n \rangle \approx 8 \times 10^5$ . The temperature related to maximum crystallization rate,  $T_{c, \max}$  is observed to be between  $-60^\circ\text{C}$  and  $-70^\circ\text{C}$ . The degree of equilibrium crystallinity of Ln-PB is independent of molecular weight at  $\langle M_n \rangle$  greater than  $10^6$ , also the linearity is shown between the correspondent temperature, degree of equilibrium crystallinity and molecular weight. (Edited author abstract) 8 refs.

Zhang, Hongfang (Acad Sinica, Changchun, China); Mo, Zhishen. *Chin J Polym Sci (Engl Ed)* v 4 n 3 Jan 1987 p 241-247.

**081135 NMR APPROACH TO THE KINETICS OF POLYMER CRYSTALLIZATION. 1. CIS-1,4-POLYBUTADIENE.** The isothermal crystallization kinetics of cis-1,4-polybutadiene (PB) in bulk, was studied over the temperature range 193 to 235 K, using  $^1\text{H}$  pulsed high-resolution FT-NMR. Analysis of the spectral line area and width, corresponding to the resonance of protons bonded to noncrystalline chain segments, yields two major results: (i) The line area variations are associated with the overall progression of crystallization in the sample, which is shown to obey an Avrami law. (ii) The line-width is assumed to be closely related to a statistical network with the average mesh size determined by a random distribution of crystallites. Finally, concomitant spin-lattice relaxation time measurements show an increase of this parameter which parallels the development of the crystalline fraction. (Edited author abstract) 39 refs.

Feio, G. (CNRS, St. Martin d'Heres, Fr); Cohen-Addad, J.P. *J Polym Sci Part B* v 26 n 2 Feb 1988 p 389-412.

**081136 STIRRING INDUCED SOLUTION CRYSTALLIZATION OF CIS-1, 4-POLYBUTADIENE.** The stirring induced solution crystallization behavior of cis-1, 4-polybutadiene polymerized with rare-earth catalyst (Ln-PB) has been studied by electron microscope, DSC and GPC. It has been found that when 0.5% Ln-PB toluene solution was stirred at a temperature within the range of  $-15^\circ$  to  $-79^\circ\text{C}$  with a speed of 180 rpm, a kind of white swollen thread-like substance wound around the stirrer was formed. It was seen under electron microscope that this swollen thread-like substance consisted of fibrillar crystals of Ln-PB parallel to each other. The amount of Ln-PB wound around the stirrer increased with the decrease in crystallization temperature. (Edited author abstract) 6 refs.

## Dielectric Properties

**081137 DIELECTRIC PROPERTIES OF 1,2-POLYBUTADIENES.** The dielectric permittivity and loss tangent of 1,2-polybutadienes with different chain structures were determined as a function of temperature from  $-180^\circ\text{C}$  to  $100^\circ\text{C}$  at different frequencies, and the

frequency and structure dependence of the dielectric properties of 1,2-polybutadienes have been investigated. It is found that a maximum of the permittivity occurs in the glass-transition region. The width of the glass-transition peak increases with increasing frequency while its height has little change. With a rise in the content of 1,2-units, the permittivity decreases and the height of the glass-transition peak grows slightly. A maximum of the width of the glass transition peak appears when the content of 1, 2-units is about 45%. Both the permittivity and dielectric loss drop as of the content of syndiotactic 1,2-units increases. (Author abstract) 10 refs.

Ni, Shaoru (Acad Sinica, Changchun, China); Yu, Fusheng; Shen, Lianfang; Qian, Baogong. *Chin J Polym Sci (Engl Ed)* v 5 n 2 1987 p 120-124.

**081138 FREQUENCY DEPENDENCE OF THE DIELECTRIC RELAXATION OF 1,2-POLYBUTADIENES.** The dielectric loss factor and permittivity of a series of 1,2-polybutadienes with different contents of 1,2-units and different contents of syndiotactic 1,2-units were determined over a frequency range from 30Hz to 100KHz at different temperatures. The WLF equation was evaluated for various samples with  $T_g$  at 100KHz as a reference temperature and the master curves of various samples have been constructed, which are in accordance with those calculated by Havriliak-Negami equation. The frequency dependence of the dielectric relaxation of 1,2-polybutadienes was investigated over a frequency range from  $10^0$  Hz to  $10^{12}$  Hz in terms of the experimental data and the master curves. (Author abstract) 7 refs.

## Diffusion

**081139 MUTUAL DIFFUSION IN BLENDS OF LONG AND SHORT ENTANGLED POLYMER CHAINS.** We have used infrared microdensitometry to study the mutual diffusion across an originally sharp interface between two saturated polybutadienes of degrees of polymerization  $N_A$  and  $N_B$  ( $N_B$  the entanglement length) for three different ratios  $N_A/N_B$ . The extent of diffusion broadening suggests that the mutual diffusion coefficient is controlled by the mobility of the faster moving (shorter) polymer chains, indicating that convective flow may be important in such mixing phenomena. (Author abstract) 30 refs.

## Failure

**081140 SEM STUDIES ON THE TEAR FAILURE OF FILLED THERMOPLASTIC 1,2 POLYBUTADIENE AND BLENDS OF 1,2 POLYBUTADIENE AND NATURAL RUBBER.** Scanning electron microscopic (SEM) examination of failure surfaces in various failure modes has been shown to be a valuable tool in understanding the mechanism of failure in rubber vulcanisates, blends and composites and also in studying the toughening mechanism of plastics and epoxies with the help of elastomers. However, such reports dealing with fracture mechanism in TPEs are quite few. This paper reports on the results of the SEM observations on the tear failure of 1,2 PBD and 1,2 PBD-NR blends containing clay and carbon black as fillers. Experiments show that clay reduces the tear strength of 1,2 PBD whereas carbon black increases it by 10%. Scanning electron microscopic investigations have shown that the tear fracture surfaces of unfilled and filled 1,2 PBD are entirely different. The effect of clay on the tear strength of 1,2 PBD-NR blends becomes more pronounced as the NR content in the blend increases. 18 refs.

## Latex

**081141 SYNTHESIS OF A POLYDISPERSED POLYBUTADIENE LATEX. DIRECT METHOD FOR HIGH-SOLID POLYBUTADIENE EMULSION PREPARATION.** A high solid, polydispersed polybutadiene latex of large particle size was synthesized. The reaction was carried out at a high monomer/water ratio and a small quantity of emulsifier (soap). Additions of a colloidal active material with a high molecular weight and an electrolyte were effective in limiting the surface film of growing polymer particles governed by water structure or ionic environment and, also, in promoting the agglomeration of particles. A mixture of sodium alginate and magnesium sulfate was particularly effective, and provided a method with excellent reproducibility. (Author abstract) 24 refs.

Araki, Yoshihiko (Nippon Oil Co, Yokohama, Jpn). *Polym J* v 19 n 7 1987 p 863-871.

## Microstructure

**081142 INTERRELATION BETWEEN THE MOLECULAR MASS AND MICROSTRUCTURE OF POLYBUTADIENE OBTAINED WITH CIS-REGULATING SYSTEMS.** It has been established that the concentration of 1,4-cis-links and the molecular mass of polybutadiene obtained with cis-regulating systems containing nickel change in a parallel fashion. The hypothesis is expressed and experimentally confirmed that the decisive role in regulating both the molecular mass and also the structure of the polybutadiene is taken by an intermediate  $\sigma$ -organometallic derivative in which there is a  $\beta_2 - \text{H}$  bond existing in a  $\sigma$ ,  $\pi$ -hyperconjugation interaction with the transition metal. (Author abstract) 29 refs.

## Molecular Weight

**081143 BIMODAL MOLECULAR WEIGHT DISTRIBUTION OF CIS-POLYBUTADIENE POLYMERIZED WITH LANTHANIDE COMPLEX CATALYSTS.** The variation of the molecular weight and molecular weight distribution of cis-polybutadiene in the course of polymerization catalyzed by lanthanide complex composed of triisobutyl aluminum or diisobutyl aluminum hydride was investigated by osmometry, viscometry and size exclusion chromatography. By analyzing the experimental data, the reasons for the appearance of bimodal molecular weight distribution were elucidated and the possible mechanisms of polymerization were discussed. (Author abstract) 9 refs.

## Performance

**081144 HIGH VINYL POLYBUTADIENE DYNAMIC PROPERTIES.** In this work, the authors show how the systematic use of the analytical expression of the superposition principle (WLF equation) allows them the evaluation of the viscoelastic behaviour performance as a function of frequency. So a more precise correlation between performance and chemical structure is obtained and some fundamental physical parameters have been evaluated. Some guidelines towards improved chemical structures are indicated. (Author abstract) 12 refs.

Gargani, L.; De Ponti, P.; Bruzzone, M. *Kautsch Gummi Kunstst* v 40 n 10 Oct 1987 p 935-937.

## Physical Properties

**081145 LOCAL DYNAMICS OF POLY(CIS-1,4-BUTADIENE) STUDIED BY COUPLED SPIN RELAXATION.** The dynamics of an entangled linear polymer, poly(cis-1,4-butadiene), are studied by the coupled spin relaxation of a methylene group ( $^{13}\text{CH}_2$ ). Relaxation experiments are performed on the solid, using magic-angle spinning, and in solution with  $\text{CD}_2\text{Cl}_2$  at concentrations of 10-80 mol% monomer. By extrapolating the data taken between 10 and 40 mol% monomer to infinite dilution, four unique spectral densities are measured for the methylene. These can be expressed in terms of correlation times describing the reorientation of d-orbital-like functions oriented along a Cartesian axis system. (Edited author abstract) 39 refs.

## Pyrolysis See Also PROPELLANTS—Materials.

**081146 EFFECT OF CARBON BLACK FILLER ON THE PYROLYSIS BEHAVIOUR OF VULCANIZED CIS-POLYBUTADIENE.** The pyrolysis-gas chromatographic analysis at 770°C of two series of vulcanized products of a standard mixture of polybutadiene Buna cis 132 as the rubber component and sulphur as the cross-linking agent, in the presence and absence of a carbon black as a filler, has been studied. In both series the density of cross-linking was varied by changing the vulcanization time. Definite correlations were found between the ratio of peak areas toluene/4-vinylcyclohexene and the degree of swelling, and the shear modulus. Curie-point pyrolysis of a third series of vulcanized products in which the carbon black content was varied between 0 and 40%, with the vulcanization time being constant (70 min), showed a distinct increase of the same ratio of peak with increasing content of carbon black and increasing mechanical strength. (Edited author abstract) 55 refs.

## Radiation Effects

**081147 MECHANICAL PROPERTIES AND FAILURE SURFACES OF GAMMA-RAY IRRADIATED SYSTEMS BASED ON THERMOPLASTIC 1,2-POLYBUTADIENE.** The effect of  $^{60}\text{Co}$  gamma-radiation on the mechanical properties of clay filled and unfilled 1,2 polybutadiene (1,2 PBD) and 1,2 PBD-natural rubber (NR) blends has been investigated. In the case of blends the effects on blend ratio and filler have been studied with reference to absorbed radiation dose varying from 0.1 to 100 Mrad at room temperature. Radiation was found to transform the flexible samples to brittle and rigid materials especially at high dose levels. The stress-strain behavior, tensile strength, elongation, tension set and crosslink density were found to be markedly affected at dose levels of 10 Mrad and above. (Author abstract) 37 refs.

Bhagawan, S.S. (Indian Inst of Technology, Kharagpur, India); Kuriakose, B.; De, S.K. *Radiat Phys Chem* v 30 n 2 1987 p 95-104.

## Rheology

**081148 RHEOLOGICAL CHARACTERIZATION OF PROCESSABILITY OF UNVULCANIZED POLYBUTADIENE.** Rheological investigation on a series of unvulcanized polybutadiene elastomers of different processability has been carried out by means of a capillary extrusion rheometer. It is found that the processability of unvulcanized polybutadiene can be correlated with the occurrence of unsteady flow and the wall stress, dependence of the dimensionless number characterizing the entrance elongational elasticity which has been found to be sensitive to the branching structure and the molecular weight distribution of the samples. Interpreta-

tions based on the structural data of unvulcanized polybutadiene were discussed. (Author abstract) 14 refs.

## Separation See POLYSTYRENES—Separation.

**Solutions** See BLOCK COPOLYMERS—Solutions; POLYSTYRENES.

## Spectroscopic Analysis

**081149 CARBON-13 NMR STUDY ON MOLECULAR MOTION OF 1,2-POLYBUTADIENE - TEMPERATURE DEPENDENCE OF MOLECULAR MOTION.** Proton-decoupled,  $^{13}\text{C}$  FT-NMR (operating at 50.3 MHz) is used to determine spin-lattice relaxation time ( $T_1$ ), nuclear Overhauser enhancement (NOE), line-width and chemical shift of 1,2-polybutadiene as a function of temperature in  $\text{CDCl}_3$  solution and the temperature dependence of molecular motion of 1,2-polybutadiene has been investigated with these NMR relaxation parameters. It is found that jumps of NOE and linewidth vs. temperature appear between -10°C and -30°C. The minimum of  $nT_1$  vs. temperature for all carbons occur at about -45°C. (Author abstract) 7 refs.

Ni, Shaoru (Acad Sinica, Changchun, China); Shen, Lianfang; Yu, Fusheng; Qian, Baogong. *Chin J Polym Sci (Engl Ed)* v 4 n 3 Jan 1987 p 235-240.

**081150 HIGH-TEMPERATURE STRUCTURAL TRANSITION OF POLYBUTADIENES.** In cis-1,4-polybutadiene IR spectroscopy, differential scanning calorimetry and the diffusion method have revealed a structural transition in the region of 55°C due to the breakdown of ordered regions. The transition found belongs to the category of liquid-liquid type transitions. The introduction into the macromolecular chains of trans-1,4- and/or 1,2-butadiene units leads to the appearance of new structural transitions. The liquid-liquid transition for such polybutadienes is in the region T approximately  $T_g \approx 150^\circ\text{C}$  where  $T_g$  is the glass transition point of the least flexible chain homopolymer the units of which are introduced into the macrochains of cis-1,4-polybutadiene. (Author abstract) 19 refs.

Sokolova, L.V. (Lomonosov Inst of Fine Chemical Technology, Moscow, USSR); Chesnokova, O.A.; Shershnev, V.A. *Polym Sci USSR* v 29 n 1 Jan 1988 p 27-34.

## Stresses

**081151 RELAXATION TRANSITIONS IN POLYBUTADIENE AND IN POLYBUTADIENE-METHYLSTYRENES.** The relaxation transitions in polybutadiene and in its copolymers with methylstyrene were studied by the methods of mechanical relaxation in the range -150+350°. In this range, up to seventeen transitions of various nature were observed, most of them connected with the butadiene component in the copolymers. The glass transition process and some copolymer-specific relaxation processes depend on the presence of the methylstyrene component in the macromolecules. (Author abstract). 15 Refs.

## Structure

**081152 PREPARATION OF ASYMMETRIC THREE-ARM POLYBUTADIENE AND POLYSTYRENE STARS.** The synthesis of three-armed polybutadiene and polystyrene stars is described for the case where one of the three arms differs in molecular weight from the remaining two. The preparative approach involves the reaction of methyltrichlorosilane with the chain end active centers under conditions unfavorable to chain coupling or linking, i.e., the synthesis of linear doublet chains or three-arm stars. Some observations regarding ther-

mal-induced post-polymerization side reactions that distort the near-monodisperse nature of the molecular weight distributions obtainable for polybutadiene are described. Preparative conditions must be selected to avoid such side reactions if 'model' branched polybutadienes are required. (Author abstract) 85 refs.

Pennisi, Robert W. (Univ of Akron, Akron, OH, USA); Fetters, Lewis J. *Macromolecules* v 21 n 4 Apr 1988 p 1094-1099.

## Synthesis See Also POLYSULFIDES—Synthesis.

**081153 SYNTHESIS AND CHARACTERIZATION OF RING POLYBUTADIENES.** It has been shown that butadiene initiated with potassium naphthalene in the mixture THF-n-hexane polymerizes conveniently rapidly. The active center is sufficiently stable below 0°C to produce narrow molecular weight linear polybutadiene. The two-ended living polymer has also served to prepare ring polybutadienes. The analysis of the ring polymers by a high-resolution set of SEC columns proved superior to the conventional method for the determination of the linear content in rings and in synthetic mixtures of rings and linear polymers. Dilute solution characterization of the linear and ring polymers shows that  $g' = [\eta]_r / [\eta]_l$  is less than 0.66 in a good solvent. (Author abstract) 28 refs.

Roovers, J. (Nat'l Research Council of Canada, Ottawa, Ont, Can); Toporowski, P.M. *J Polym Sci Part B* v 26 n 6 Jun 1988 p 1251-1259.

**081154 SYNTHESIS AND PROPERTIES OF ELASTOMERIC IONENES: I. POLYBUTADIENE IONENES.** Polybutadiene ionene (PBI) carrying quaternary ammonium ions in the main chain was synthesized from dimethylamino-terminated polybutadiene and 1,4-dibromobutane. Dimethylamino-terminated polybutadiene was prepared by the reaction of isocyanate-terminated polybutadiene with 2-dimethylaminoethanol. The swelling property and the mechanical properties of PBI were compared with those of polybutadiene urethane (PBU), which was prepared by the reaction of hydroxy-terminated polybutadiene with a diisocyanate. The following points were found: (1) PBI shows almost the same solubility parameter as that of PBU; (2) PBI attains a four time greater tensile strength at break than PBU at room temperature; (3) PBI shows a thermoplastic behavior. (Edited author abstract) 16 refs.

**081155 FUNCTIONAL MONOMERS AND POLYMERS. CLVI. ASYMMETRIC INCLUSION POLYMERIZATION OF 1,3-BUTADIENE DERIVATIVES WITH POLAR SUBSTITUENTS IN A DEOXYCHOLIC ACID CANAL.** Asymmetric inclusion polymerization using a chiral host molecule is a convenient and excellent way for obtaining stereoregular and optically active polymers. In a series of extensive studies on the inclusion polymerization of diene monomers using deoxycholic acid (3 $\alpha$ , 12 $\alpha$ -dihydroxy-5 $\beta$ -cholan-24-oic acid; DCA) and its derivative, apocholic acid as host molecules, we found a critical role of thermally stable propagating radicals and a polymerizability of butadiene derivatives with bulky substituents. With respect to 1,3-butadiene derivatives with polar substituents, there are only a few successful studies on asymmetric polymerization, but no study on asymmetric inclusion polymerization. In this communication we report the first examples of asymmetric inclusion polymerization of the monomers in a DCA canal. 22 refs.

**081156 SYNTHESIS OF CIS-1,4-POLYBUTADIENE WITH NICKEL CATALYST: INVESTIGATIONS ON INTERACTIONS BETWEEN THE CATALYTIC COMPONENTS BY USING UV-VIS SPECTRUM.** Ni(II) naphthenate in hydrogenated gasoline or toluene will appear light green, which is the result of absorption in the red and blue bands of the spectrum. The three peaks caused by the spin-allowed d-d transitions are 403, 680, and 1170 nm respectively, and are similar to those of  $Ni(H_2O)_6^{+2}$ . The configuration of Ni(II) complex is octahedral. In a two-component system of  $Ni(naph)_2-Al(i-Bu)_3$ , the naphthenate ligand attached to Ni(II) can be exchanged for the alkyl group on tri-isobutylaluminum, if  $Al(i-Bu)_3/Ni(naph)_2$  in a system containing metalalkyl and naphthenate does not exceed the value of 0.53. In a two-component system  $Ni(naph)_2-BF_3 \cdot OEt_2$ , a part of the naphthenate can be exchanged for halogen. A new Ni(II) complex is formed, which consists of three new d-d bands in the region 360-1660 nm. (Author abstract) 7 refs.

## Thermal Properties

**081157 SOME SPECIFIC PROPERTIES OF DICARBOXYLATE POLYMERS BASED ON Al AND Ti METAL IONS.** Neutralization of carboxyl-terminated polybutadienes with tri- or tetravalent metal was carried out with different ratios of the corresponding neutralizing agents. The network structures of the prepared materials were investigated through their molecular, thermal, dynamic, mechanical, and dielectric properties. The nature, the density, and the efficiency of the ionic interactions influence the solubility, the formation, and the thermal stability of the three-dimensional cross-linked ion-containing polymers. (Author abstract) 23 refs.

## Viscoelasticity

**081158 EFFECTS OF POLYDISPERSITY ON THE LINEAR VISCOELASTIC PROPERTIES OF ENTANGLED POLYMERS. 3. EXPERIMENTAL OBSERVATIONS ON BINARY MIXTURES OF LINEAR AND STAR POLYBUTADIENES.** The effect of polydispersity on the viscoelastic response of entangled polymers was explored with binary mixtures of nearly monodisperse linear and 3-arm star polybutadienes. Storage and loss moduli were measured over a wide range of frequencies for one series of star-star mixtures and four series of linear-star mixtures. Results at several temperatures were reduced to master curves at 25°C, and the values of viscosity and recoverable compliance were obtained. Some observations about the influence of the matrix on the relaxation of individual components are recorded and compared with results from other laboratories. The dependences of the viscosity and recoverable compliance on composition when one or both of the components is a star polymer are described. (Author abstract) 33 refs.

Struglinski, Mark J. (Northwestern Univ, Evanston, IL, USA); Graessley, William W.; Fetters, Lewis J. *Macromolecules* v 21 n 3 Mar 1988 p 783-789.

**081159 VISCOELASTIC PROPERTIES OF POLYBUTADIENE RINGS.** The linear viscoelastic properties of a series of linear and three ring polybutadienes have been studied. It is observed that melt viscosity of a pure ring is about 10 times smaller than that of the linear polymer with the same molecular weight. The plateau modulus is similarly 5 times smaller. Rings contaminated with 20-25% linear polymer have the same melt viscosity as linear polymers, although their plateau modulus is only about one-half times that of the linear polymer. Synthetic mixtures of ring and linear polymers were used to complete a study of the effect of linear impurities on the melt properties of rings. The data are compared with data

obtained previously on polystyrene ring samples. (Author abstract) 36 refs.

## POLYBUTENE

**Adhesion** See THERMOPLASTICS—Adhesion.

## Blending

**081160 POLYBUTYLENE BLENDS AS EASY OPEN SEAL COATS FOR FLEXIBLE PACKAGING AND LIDDING.** A controllable heat sealing technology, based on blends of DURAFLEX polybutylene polymer (poly-1-butene) with low density polyethylenes, ethylene-vinyl acetate copolymers (EVA) and other polyolefins is discussed. A variety of systems are described which provide easy-open or peelable seals on various substrates for both flexible packaging and lidding. The blends are 100% solid (solvent free) and can be processed on standard equipment. The peeling mechanism and variables which permit tailoring of seal strength are discussed. Examples of material structures for various applications are described, including suggested fabrication techniques. (Author abstract) 5 refs.

## Chemical Analysis

**081161 CALORIMETRIC EVIDENCE OF THE INTERCHANGE IN PHENOXY/POLY(BUTYLENE TEREPHTHALATE) BLENDS.** Interchange reactions taking place at high temperatures in phenoxy/poly(butylene terephthalate) blends have been studied by differential scanning calorimetry. Results show the influence that these types of reactions have on the thermal transitions of the blends. These results may be explained on the basis of a reaction between hydroxyl groups in phenoxy and ester groups of poly(butylene terephthalate), causing the formation of grafted and crosslinked copolymers. (Author abstract) 21 refs.

Eguiazabal, J.I. (UPV, San Sebastian, Spain); Cortazar, M.; Iruin, J.J.; Guzman, G.M. *J Macromol Sci Phys* v B27 n 1 Apr 1988 p 19-30.

## Crystallization

**081162 CRYSTALLIZATION BEHAVIOR OF POLYBUTENE-1 IN THE ANISOTROPIC SYSTEM BLENDED WITH POLYPROPYLENE.** Development of supermolecular structure in drawn polypropylene (PP)/polybutene-1 (PB-1) blends was studied. PP (matrix)/PB-1 (70/30) blend films were drawn and heat-treated at fixed length or free ends at temperatures above the melting point of PB-1. It was found that a long axis of the PB-1 lamella is aligned perpendicular to the draw direction, and the c-axis of the PB-1 crystal is oriented perpendicular both to the draw direction and the plane of the surface of the blend film. The kinetics of isothermal crystallization of PB-1 was examined by use of a DSC technique. The result supports the conclusion that the heterogeneous nucleation of PB-1 followed by 2-dimensional crystal growth prevailed in oriented PP/PB-1 blend film. (Edited author abstract) 15 refs.

Takahashi, T. (Fukui Univ, Bunkyo, Jpn); Nishio, Y.; Mizuno, H. *J Appl Polym Sci* v 34 n 8 Dec 1987 p 2757-2768.

## Fractionation

**081163 PREPARATIVE GPC IN FUNDAMENTAL POLYMER SYNTHESIS.** A simple efficient preparative gel permeation chromatography assembly (prep GPC) has been built using largely commercially available components, (i.e., pump, columns, all glass solvent recirculating system) and its usefulness in fundamental polymer synthesis was demonstrated. The operating cost of prep GPC has

been reduced and the safety much improved by the use of n-hexane as the mobile phase. Rapid one-recycle narrow fractionation ( $M_w/M_n=1.1-1.2$ ) and purification of relatively large quantities (up to 20 g/ loading) of polyisobutylene (PIB) samples is described. Operating parameters and efficiency are illustrated by examples. By the use of this equipment sufficient quantities of narrow molecular weight distribution (MWD) polyhydrocarbons can be conveniently and rapidly obtained for meaningful structure/property research. (Edited author abstract) 3 refs.

## Solutions

**081164 ANOMALOUS LATERAL MIGRATION OF A RIGID SPHERE IN TORSIONAL FLOW OF A VISCOELASTIC FLUID - EFFECT OF POLYMER CONCENTRATION AND SOLVENT VISCOSITY.** In previous papers the authors studied the behavior of a rigid sphere entrained in torsional flow of a polymer solution held between a rotating disk and a stationary plate. In this paper the authors deal with the effects of polymer concentration (c) and solvent viscosity ( $\eta_s$ ) using the same apparatus. Blends of polybutene (PB) (Amoco H-50 and H-300) were made viscoelastic by dissolving a small amount of polyisobutylene (PIB) (Enjay Vistanex L-120,  $M_w=1.5 \times 10^6$  with a large polydispersity) with reagent grade heptane as a co-solvent. Polystyrene-divinylbenzene microspheres with a density of 1.05 g/cc were used. Since it was shown that the location of the critical streamline, separating regions of inward and outward migration, was virtually identical for different sizes of particles, the authors used one particle having a diameter of 450 microns as determined by optical microscopy. 10 refs.

## Spectroscopic Analysis

**081165 HIGH-RESOLUTION SOLID-STATE  $^{13}C$  NMR STUDY OF THE  $\alpha$  AND  $\beta$  CRYSTALLINE FORMS OF POLY(BUTYLENE TEREPHTHALATE).** Uniaxially strained poly(butylene terephthalate) (PBT) undergoes a reversible  $\alpha$  and to  $\beta$  crystalline phase transition, where the fiber repeat distance is increased in the  $\beta$  phase. The question of what the intrachain conformations of PBT are in both relaxed  $\alpha$  and strained  $\beta$  crystalline phases has not yet received a completely satisfactory answer. We have performed variable-temperature  $^{13}C$  CP/MAS NMR measurements on both crystalline phases of PBT in the hope that their high-resolution solid-state spectra would permit us to compare the crystalline chain conformation in the  $\alpha$  and  $\beta$  phases. In the spectra recorded between ambient temperature and ca. 90-100°C, all resonances are broadened by contributions from the amorphous PBT chains. (Edited author abstract) 25 refs.

## Synthesis

**081166 ELECTROPHILIC SUBSTITUTION OF ORGANOSILICON COMPOUNDS. II. SYNTHESIS OF ALLYL-TERMINATED POLYISOBUTYLENES BY QUANTITATIVE ALLYLATION OF TERT-CHLORO-POLYISOBUTYLENES WITH ALLYL-TRIMETHYLSILANE.** Essentially quantitative allylation of linear and three-arm star tert-chloro capped polyisobutylenes [ $^{13}C$ -PIB-Cl] and PIB(Cl) $_3$ ] has been achieved by the use of allyltrimethylsilane (AllylSiMe $_3$ ) and Friedel-Crafts acids. Quantitative allylation occurs under suitable conditions, e.g., slight molar excess of TiCl $_4$  and AllylSiMe $_3$ , polar media, -70°C. These conditions have been developed from quantitative model allylation experiments using 2,4,4-trimethyl-2-chloropentane. While allylation proceeds with great ease under the

mildest conditions, etc.,  $-70^{\circ}\text{C}$ , vinylation with vinyltrimethylsilane could not be achieved even under more forcing conditions. (Edited author abstract) 23 refs.

**081167 POLY-1-BUTENE: ITS PREPARATION, PROPERTIES AND CHALLENGES.** More than 30 years after the synthesis of isotactic poly-1-butene there is still no large commercial production of the resin, nor major applications to compare with those of the lighter olefin polymers polyethylene and polypropylene. The chief reason for the slower commercialization has been the low level of monomer availability and its higher price compared with ethylene and propylene. However, poly-1-butene has several highly attractive properties. It is tough, retains strength at elevated temperatures, is resistant to stress cracking and abrasion, and exhibits good long-term creep resistance and strength even at elevated temperatures. This paper reviews the preparation, properties and challenges of poly-1-butene. 166 refs.

**081168 HOLE TRANSPORT OF TRANS-1,2-BIS-CARBAZOLYL-CYCLOBUTANE-DOPED POLY(BISPHENOL A CARBONATE) FILM.** The hole transport of trans-1,2-biscarbazolylcyclobutane (CB)-doped poly(bisphenol A carbonate) (PC) film has been investigated in the CB concentration range of  $3.8 \times 10^{-4}$  mol  $\text{cm}^{-3}$  (912 wt%) to  $1.6 \times 10^{-3}$  mol  $\text{cm}^{-3}$  (51 wt%). The hole mobility increased drastically with increasing CB concentration. The hole mobility was analyzed by a random hopping model. The localization radius  $p_0$  of the CB/PC system was 1.9 Å, which is larger than that obtained for the N-isopropyl-carbazole-doped PC system. The highest hole mobility of  $2.9 \times 10^{-6}$   $\text{cm}^2 \text{V}^{-1} \text{s}^{-1}$  was obtained when the CB concentration was  $1.6 \times 10^{-3}$  mol  $\text{cm}^{-3}$  (51 wt%) at  $E = 1.6 \times 10^5$  V  $\text{cm}^{-1}$  and  $T = 298$  K. ## Adsorption

**081169 ADSORPTION OF OLIGO- AND POLY-CARBONATES ON THE AQUEOUS SOLUTION OF ALKALI-ORGANIC SOLVENT PHASE BOUNDARY.** The values of the surface activity and Gibbs adsorption were determined with the interfacial tension isotherms of solutions of oligo- and polycarbonates in an organic solvent on the interface with aqueous solutions of alkali. It was found that an increase in the basicity of the aqueous phase results in an increase in the adsorption capacity of the polycarbonates. The effect of the structure of the oligomers on their surface activity was examined. The dependence of adsorption of the polycarbonates on the composition of the organic solvent was studied. (Author abstract) 10 refs.

## Anisotropy

**081170 STRUCTURE AND ANISOTROPY IN PC: II. WAXS, ANISOTROPIC HEAT CONDUCTION AND BIREFRINGENCE IN ORIENTED SAMPLES.** Birefringence, anisotropic heat conduction, and wide angle X-ray scattering (WAXS) investigations have been performed on one set of uniaxially drawn samples of polycarbonate (PC). The orientation parameters from heat

conduction and from WAXS are well correlated. The intrinsic birefringence is determined to  $\Delta n_0 = 0.106$  in agreement with the monomer polarizability calculated on the basis of model structures. The short range order as evidenced by WAXS does not depend on the degree of orientation in PC. Over small regions ( $\leq 1.5$  nm) the molecular arrangement is similar to that in the crystalline state. (Author abstract) 21 refs.

Applications See NEUTRONS—Detectors.

## Biocompatibility

**081171 PROTEIN-POLYMER INTERACTION. CHANGES WITH PLASMA COMPONENTS, VITAMINS, AND ANTIPLATELET DRUGS AT THE INTERFACE.** The authors have reviewed the relevance of the surface modification of polymers to improve blood compatibility. In the present paper the authors report the need for pharmaceutical modification of blood itself to enhance the antithrombogenic character of the substrate. The totality of earlier observations with other preliminary studies carried out in the author's laboratory relevant to this system are reviewed. Such a synthesis relates both to the fundamental aspects of interaction and its relationship to blood-material interactions, interrelating this work with the established results from the literature. 150 refs.

Blending See Also COPOLYMERS—Blending; INTERPENETRATING POLYMER NETWORKS—Mechanical Properties; POLYMERS—Mechanical Properties.

**081172 MISCIBLE BLENDS OF POLYCARBONATE AND POLYMETHYL METHACRYLATE.** Solvent-cast films of polycarbonate (PC) polymethyl methacrylate (PMMA) mixtures exhibit a single-phase structure with outstanding optical clarity. Differential scanning calorimetry (DSC) studies show a single glass transition in the intermediate blends. However, the blends undergo phase separation upon heating above  $240^{\circ}\text{C}$ . The phase diagram has been established subsequently by means of a cloud point method and is reminiscent of lower critical solution temperature (LCST) in character. (Author abstract) 14 refs.

Kyu, Thein (Univ of Akron, Akron, OH, USA); Saldanha, Jeanne M. *J Polym Sci Part C* v 26 n 1 Jan 1988 p 33-40.

**081173 MORPHOLOGICAL STUDIES OF POLY-CARBONATE-POLYBUTYLENE TEREPHTHALATE) BLENDS BY TRANSMISSION ELECTRON MICROSCOPY.** The morphology of polycarbonate (PC)-poly(butylene terephthalate) (PBT) blends prepared by melt-processing in an extruder or a Brabender Plastograph was studied by Transmission Electron Microscopy. Transesterification during blending was avoided by the use of di-n-octadecyl phosphite, an efficient transesterification inhibitor. Ruthenium tetroxide was used to selectively stain the PC fraction. A preliminary study of the morphology as a function of composition and thermal annealing was carried out. (Edited author abstract) 34 refs.

Delimoy, Didier (Univ Catholique de Louvain, Louvain-la-Neuve, Belg); Bailly, Christian; Devaux, Jacques; Legras, Roger. *Polym Eng Sci* v 28 n 2 Jan 1988 p 104-112.

**081174 BLEND MISCIBILITY OF BISPHENOL-A POLYCARBONATE AND POLY(ETHYLENE TEREPHTHALATE) AS STUDIED BY SOLID-STATE HIGH-RESOLUTION  $^{13}\text{C}$  NMR SPECTROSCOPY.** Blends of poly(ethylene terephthalate) (PET) and bisphenol-A polycarbonate (BPAPC), cast as films from solution in a mixture of hexafluoro-2-propanol and dichloromethane, pressed as a film, and then quenched in ice

water, were examined with solid-state high-resolution  $^{13}\text{C}$  NMR spectroscopy and differential scanning calorimetry. As prepared, the samples contained separated domains of amorphous PET and BPAPC exceeding 150 Å in size. Heating to  $265^{\circ}\text{C}$  for about 4 min, followed by cooling in air or in a metal heating block, resulted in crystallization of part of the PET. Further heating and cooling cycles resulted in degradation of the size of the PET crystals while fragments derived from PET were mixed at the molecular level with those derived from BPAPC. (Edited author abstract) 79 refs.

## Bonding

**081175 SAFER AND BETTER BONDING OF POLYCARBONATE PARTS.** Ethylene dichloride and methylene chloride are most commonly used for solvent-welding polycarbonate medical assemblies. Recent OSHA regulations restricting the use of these solvents are exerting increasing pressure on manufacturers to replace them with alternative methods and materials. One option is to use different solvents. UV-curing adhesives offer another option. Ways of joining polycarbonate to other materials, particularly in the difficult case of PVC tubing, also concurrently interest manufacturers of medical devices. Alternative solvents, cyanoacrylates, and UV-curing adhesives hold out special promises for these applications too.

Licata, Mark (Mobay Corp, Pittsburgh, PA, USA); Glogovsky, Todd; Haag, Earl. *Plast Eng* v 43 n 10 Oct 1987 p 35-38.

## Calculations

**081176 CHAIN CONFORMATIONS OF POLY-CARBONATE FROM AB INITIO CALCULATIONS.** Ab initio calculations with full geometry optimization on diphenyl carbonate (DPC) and diphenylpropane (DPP) are carried out to determine the bond geometries and the conformational energies and then to compute the unperturbed chain dimensions of the polycarbonate of 2,2-bis(4-hydroxyphenyl)propane, or bisphenol A polycarbonate. The bond geometries calculated with the 6-31G\* basis sets are in excellent agreement with the experimental values. The conformational energy contours exhibit a rather low energy barrier (ca. 1.9 kcal/mol) in DPP and a nearly flat profile in DPC for the rotations of phenylene groups. (Edited author abstract) 22 refs.

Laskowski, Bernard C. (Analatom Inc, San Jose, CA, USA); Yoon, Do Y.; McLean, Doug; Jaffe, Richard L. *Macromolecules* v 21 n 6 Jun 1988 p 1629-1633.

## Crack Propagation

**081177 FATIGUE CRACK PROPAGATION AND CRACK CLOSURE BEHAVIOR IN POLYCARBONATE AND FIBER REINFORCED POLYCARBONATE.** Fatigue crack propagation was investigated in polycarbonate and glass fiber reinforced polycarbonate and the effect of stress ratio and glass fiber content determined. The addition of glass fiber increases the tensile strength, but does not always contribute to an increase in fatigue crack propagation resistance. For polycarbonate, the effect of stress ratio can be partly explained by using crack closure concepts as other researchers have suggested, but for glass fiber reinforced polycarbonate this was not possible. Fractography revealed a void growth process, which occurred by decohesion at the interface of the glass fibers and the base material, which was dependent on the maximum stress intensity factor. (Edited author abstract) 10 refs.

Murakami, R. (Univ of Tokushima, Tokushima, Jpn); Noguchi, S.; Akizono, K.; Ferguson, W.G. *Fatigue Fract Eng Mater Struct* v 10 n 6 1987 p 461-470.

## Crystallization

**081178 CRYSTALLINE MEMORY ON POLYCARBONATE.** A significant reduction on the time for thermal crystallization of Bisphenol-A polycarbonate has been achieved by means of a previous crystallization step of the polymer in acetone, followed by a capillary extrusion processing at temperatures above its melting range (230-280°C). The crystallinity of PC was corroborated qualitatively by means of WAXS and quantitatively by means of DSC. The acetone-crystallized polymer showed higher values of dynamic viscosity than its amorphous counterpart. Such difference decreased with the increase of the test temperature and disappeared at 280°C. The degree of crystallinity of thermally crystallized PC increased with the decrease of the capillary extrusion temperature of the acetone-crystallized material. It is inferred that the time-temperature-dependent long range molecular diffusion necessary for the total melting of the crystal fractions could not take place entirely for the short times employed ( $\approx 4$  min), allowing the extruded polymer to behave as a self-nucleated material. (Author abstract) 11 refs.

Di Filippo, Giuseppe V. (Univ Simon Bolivar, Caracas, Venez); Gonzalez, Maria E.; Gasiba, Maria T.; Muller, Alejandro V. *J Appl Polym Sci* v 34 n 5 Oct 1987 p 1959-1966.

## Deformation

**081179 DEVELOPMENT OF ORIENTATION IN GLASSY POLYCARBONATE AT HIGH STRAINS.** Birefringence has been measured on yielded specimens of polycarbonate in simple tension in creep and stress relaxation. The pseudo-affine and random-chain affine models both fail to describe the experimental relationship between birefringence (or orientation) and strain. A new model assuming affine deformation of chain ends and non-random chains is presented, adequately describing the trends of experimental data. (Author abstract) 37 refs.

Heymans, Nicole (Univ Libre de Bruxelles, Brussels, Belg). *Polymer* v 28 n 12 Nov 1987 p 2009-2017.

**081180 REVERSAL AND ACTIVATION OF PHYSICAL AGING BY APPLIED DEFORMATIONS IN SIMPLE COMPRESSION AND EXTENSION.** The differential (incremental) storage modulus  $E'$  was measured intermittently at 1 Hz during the stress relaxation of cylindrical specimens of polycarbonate subjected to finite static strains in both simple compression and extension. (In measuring  $E'$ , the amplitude of the applied sinusoidal strain was 0.2%). Application of each static strain gave a value of  $E'/E'$  less than unity, where  $E'_0$  is the storage modulus at 1 Hz of the undeformed specimen. This behavior results from an increase in the mobility of short molecular segments; it signifies a partial erasure of the state of physical aging, a change also termed de-aging or rejuvenation. After a static strain had been applied,  $E'$  increased continuously, a reflection of physical aging that results from a progressive decrease in segmental mobility. Plots of  $E'/40$  at an aging time of 100 s against the absolute value of the static strain show that simple extension de-ages a specimen somewhat more than does a strain of the same magnitude in compression. (Edited author abstract) 18 refs.

Smith, T.L. (IBM, San Jose, CA, USA); Levita, G.; Moonan, W.K. *J Polym Sci Part B* v 26 n 4 Apr 1988 p 875-881.

**081181 SUBSTRATE DEFORMATION STUDIES ON IMPACT EROSION AND PLOWING BY PHOTOELASTICITY.** Static and dynamic photoelasticity methods were applied in studying the mechanisms of erosion. A multiple spark camera and a linear gas gun were used to photograph impact-induced dynamic stress waves. The propagation of stress waves in a polycarbonate material was analyzed upon impact of a 3-mm-diameter rigid ball traveling at 50 m/s velocity. The role of pressure, shear, and Rayleigh waves in causing damage was found to be low. The residual stress field generated due to particle impact was determined using a circular polariscope. It was found that the plastic deformation at

impact-induced high strain rates and the residual stress field generated by repeated impacts produce cracking, and the interaction of these cracks results in erosion loss. Impact on brittle Columbia resin, produced lateral, circumferential, and radial cracks, resulting in material removal. The stress gradient and cracking were also studied during plowing on the above two materials. (Author abstract) 11 refs.

Naim, M. (Iowa State Univ, Ames, IA, USA); Bahadur, S. *J Elastomers Plast* v 20 n 1 Jan 1988 p 21-35.

## Degradation

**081182 SYNTHESIS, CHARACTERIZATION, AND WEATHERING BEHAVIOR OF POLYCARBONATES DERIVED FROM 3,3'-DIHYDROXYDIPHENYL ETHER.** Previous studies of the photodegradation of bisphenol A polycarbonate (BPA PC) indicate that both alkyl side chain and ring oxidation play significant roles. In order to determine the relative importance of these two pathways in the photoyellowing that accompanies photodegradation, side chain free polycarbonates based on 3,3'-dihydroxydiphenyl ether were synthesized and tested. Both accelerated weathering experiments using a QUV test apparatus and outdoor weathering indicated that these polymers photoyellowed faster than BPA PC. This suggests that ring oxidation is an important source of photoyellowing of aromatic polycarbonates. (Author abstract) 8 refs.

## Drawing and Stamping

**081183 LATENT ENERGY OF DEFORMATION OF BISPHENOL A POLYCARBONATE.** The thermodynamic behavior of poly(bisphenol A carbonate) (PC) during uniaxial cold drawing and the properties of the drawn polymer were examined. Isothermal deformation calorimetric measurements were made during the drawing process. The deformation calorimeter measures heat, work, and internal energy changes for deformation. It was found that PC exhibited nonideal plasticity with approximately 50-80% of the work of deformation dissipated as heat. The remainder of the work of deformation was stored as a latent internal energy change. The value of the internal energy change was dependent on strain rate at 20°C but was not strongly dependent on temperature in the range 20-65°C. Thermomechanical measurements on cold-drawn PC samples demonstrated striking behavior at temperatures far below the glass transition temperature  $T_g$ . Stress-temperature experiments showed that the stress increased for uniaxially constrained samples, and this stress increase began at temperatures just above the deformation temperature. Additional experiments indicated that the changes which took place during cold drawing were physical in nature and were thermoreversible. These changes in physical properties are related to those which occur due to physical aging below  $T_g$ . (Author abstract) 37 refs.

Adams, G.W. (Univ of Massachusetts, Amherst, MA, USA); Farris, R.J. *J Polym Sci Part B* v 26 n 2 Feb 1988 p 433-445.

## Elasticity

**081184 STRUCTURE AND ANISOTROPY IN POLYCARBONATE. III. STUDY OF ELASTIC AND OPTICAL PROPERTIES OF ORIENTED SAMPLES WITH THE METHOD OF HIGH RESOLUTION BRILLOUIN SPECTROSCOPY.** High resolution Brillouin spectroscopy (BS) has been used to investigate elastic and optical properties of uniaxially drawn samples of polycarbonate (PC). The results are discussed in the framework of the single phase aggregate model (SPAM) of Ward. According to a recently developed evaluation technique, the SPAM parameters of PC are determined, resulting in the elastic constants of the structural units. A nearly quadratic dependence of the orientation parameter  $P_4$  on  $P_2$  results, which can be explained by a modified

pseudoaffine deformation scheme. (Edited author abstract) 22 refs.

## Etching

**081185 INTERNAL HEATING EFFECT DURING ELECTROCHEMICAL ETCHING OF LEXAN POLYCARBONATE.** An internal heating effect has been observed during electrochemical etching of Lexan polycarbonate even at low frequencies ( $< \text{kHz}$ ). There is a correlation between the registration efficiency or detector response and the heating rate in Lexan and the two maxima occur at the same ac field frequency. The detector response also depends upon temperature, and at higher temperatures the maxima shifts towards higher frequencies. The study reveals that dielectric polarization exhibits a resonance type phenomena with applied ac field. (Author abstract) 9 refs.

**081186 RELATION BETWEEN INTERNAL HEATING EFFECT & TRACK DENSITY DURING ELECTRO-CHEMICAL ETCHING OF LEXAN POLYCARBONATE.** During electro-chemical etching of Lexan polycarbonate, heat generation takes place even at low frequencies ( $< \text{kHz}$ ). A correlation between detector response (tracks/cm<sup>2</sup>) and the heating rate has been observed. The study indirectly reveals the relation between track density and polymer loss index ( $\epsilon' \tan \delta$ ). (Author abstract) 4 refs.

Chand, Ravi (Guru Nanak Dev Univ, Amritsar, India); Virk, H.S. *Indian J Pure Appl Phys* v 25 n 5-6 May-Jun 1987 p 237-238.

## Film

**081187 PROPERTIES OF CONDUCTIVE POLYCARBONATE FILMS RETICULATE DOPED WITH MPHT(TCNQ)<sub>2</sub> AND PrPht(TCNQ)<sub>2</sub> SALTS: A HIGHLY-CONDUCTIVE FORM OF PrPht(TCNQ) BY CRYSTALLIZATION IN A POLYMER MATRIX.** Conductive polymer films obtained by reticulate doping with N-methyl phthalazinium (MPht) and N-propyl phthalazinium (PrPht) TCNQ complex salts are investigated. It is found that the spectral, electrical and magnetic properties of the MPht(TCNQ)<sub>2</sub> in a polymer matrix are not significantly different from the properties of single crystals, while in the case of PrPht a new highly-conductive form is obtained by rapid crystallization during film casting. It is concluded that the dimerization of the TCNQ stacks in the new form is not as strong but the disorder is higher as compared with single crystals of PrPht(TCNQ)<sub>2</sub>. It is possible that the stoichiometry is also different. (Author abstract) 9 refs.

## Flame Resistance

**081188 INTUMESCENT FLAME RETARDANTS FOR POLYMERS. IV. THE POLYCARBONATE-AROMATIC SULFONATES SYSTEM.** The mechanism of action of aromatic sulfonates as flame retardant (FR) agents on poly(bis-phenol-A carbonate) (PC) has been investigated. These compounds are capable of inducing a self-extinguishment in PC even when present in very low amounts (0.2-1%). Thermogravimetric and flash pyrolysis-GC-MS data show the thermal degradation rate of PC was enhanced and the distribution of the volatile pyrolysis products was modified by these additives. Oxygen Index (OI) and Nitrous Oxide Index (NOI)

measurements indicate a FR condensed-phase mechanism of these additives. (Edited author abstract). 26 Refs.

## Fracture

**081189 UNIFIED TREATMENT OF STATIC FRACTURES IN NOTCHED AND CRACKED SPECIMENS OF POLYCARBONATE.** The brittle fracture behavior in the static tension of notched specimens of polycarbonate has been studied for a wide range of notch tip radii. The nominal stress at the brittle fracture decreases with decreasing notch tip radius, and it approaches a constant value when the notch tip radius is less than about 0.1 mm. For notch tip radii less than 0.1 mm, the fracture is well explained on the basis of linear elastic fracture mechanics. For notch tip radii larger than 0.1 mm, the specimens failed in an apparently brittle manner after the formation of a small plastic zone at the notch tip. The experimental results of these specimens have been discussed in terms of a combination of the critical maximum elastic stress and the notch tip radius from the standpoint of linear notch mechanics. It is shown that the maximum elastic stress for brittle fracture is governed by the notch tip radius alone. (Author abstract) In Japanese. 15 refs.

**081190 POLYMER FATIGUE FRACTURE DIAGRAMS: BPA POLYCARBONATE.** A fatigue fracture diagram for BPA polycarbonate has been created from fatigue lifetime data obtained from knit line notched samples. This fatigue fracture diagram maps out stress-temperature zones where fatigue fracture is dominated by crack growth through leading crazes and zones where fatigue fracture occurs through shear fracture at 45 degrees to the load direction. Both craze and shear planes coexist in the fatigue crack tip plastic zone, and both compete to determine the ultimate crack growth behavior. The shear planes preferentially develop (and fracture) at higher temperatures and stresses, but this fracture process is quite slow. Consequently, an inversion in the fatigue lifetime curve is observed, with longer lifetimes at higher stresses. (Edited author abstract) 14 refs.

## Heat Treatment

**081191 ANNEALING OF REJUVENATED POLYCARBONATE.** The effect of mechanically rejuvenated samples of polycarbonate below  $T_g$  has been investigated by differential scanning calorimetry. All the traces exhibited a broad sub- $T_g$  exotherm, preceded in some cases by a small sub- $T_g$  endothermal peak. The position of the exotherm on the scan is strongly dependent on the annealing conditions. A method is proposed to obtain the value of the structural temperature characterizing any annealed rejuvenated sample, since in the authors' opinion this is the chief quantity to be adopted in annealing investigations. Basic relations are chosen to be as simple as possible, containing only three parameters optimized using previous enthalpy relaxation data obtained on samples annealed after quenching. From the same relations, traces related to annealed rejuvenated samples are computed. (Edited author abstract) 12 refs.

## Hydrolysis

**081192 POLYMERIZATION BY PHASE TRANSFER CATALYSIS: 7. EFFECT OF THE CATALYST ON THE HYDROLYSIS OF BISPHENOL A POLY-**

**THIOCARBONATE.** The hydrolysis of bisphenol A polythiocarbonate is studied under phase transfer conditions, and occurs principally in the organic phase, influenced by the catalysts according to their structure. (Author abstract) 3 refs.

Tagle, L.H. (Catholic Univ of Chile, Santiago, Chile); Diaz, R.; De La Maza, M.P. *Polym Bull (Berlin) v 18 n 6 Dec 1987 p 485-486.*

**081193 HYDROLYSIS OF POLYCARBONATE/POLYBUTYLENE TEREPHTHALATE BLEND.** The hydrolysis of a polycarbonate/polybutylene terephthalate (PBT) blend (50/50) was investigated by immersing molded samples in water baths between 21 and 98°C. Samples were also placed in a 100°C air circulating oven (dry environment). Changes in impact properties, dynamic mechanical properties, molecular weight, and thermal properties were followed. In 80°C water bath the material was found to embrittle in five to six days, and in circulating air oven at 100°C in less than 90 days. A sharp decline in molecular weight and changes in thermal and mechanical properties were observed. The activation energy for the embrittlement process in water was found to be 22 kcal/mole. This value is between the activation energy for the hydrolysis of PC and that of PBT. (Author abstract) 13 refs.

## Measurements

**081194 DISTRIBUTION OF CORRELATION TIMES IN GLASSY POLYMERS FROM PULSED DEUTERON NMR.** Pulsed deuteron NMR offers new possibilities for the determination of the distribution of correlation times for local motions in glassy polymers. The NMR line shape is a superposition of spectra corresponding to the different values of the correlation times. The weighting factors of these single spectra depend on the distribution function, which therefore can be characterized by a line shape analysis. Moreover, by combination with spin-lattice relaxation experiments the motional behaviour can be probed on a much longer time scale than by a line shape analysis alone. In this way homogeneous and heterogeneous distributions can clearly be distinguished. The method is explained in detail and is demonstrated by a simple example involving the methyl group rotation in glassy polycarbonate. (Edited author abstract) 26 refs.

## Mixing

**081195 PHASE SEPARATION BY SPINODAL DECOMPOSITION IN POLYCARBONATE/POLY(METHYL METHACRYLATE) BLENDS.** Early and late stages of phase separation by spinodal decomposition in mixtures of polycarbonate (PC) and poly(methyl methacrylate) (PMMA) were investigated by time-resolved light scattering. The PC/PMMA blend reveals a miscibility window reminiscent of an LCST (lower critical solution temperature) character. A high level of interconnectivity in the domain structure was observed in optical microscopic investigations. The time evolution of scattering halo was followed as a function of temperature jump ( $\Delta T$ ). The early stage of spinodal decomposition at low  $\Delta T$  reasonably follows the linearized Cahn-Hilliard's theory; however, deviations are seen at large temperature jumps. (Edited author abstract) 42 refs.

**081196 THE WORLD OF POLYCARBONATES.** Polycarbonates (PCs), known for toughness in molded parts, typify the class of polymers known as engineering thermoplastics (ETPs). These materials, designed to replace metals and glass in applications demanding strength and temperature resistance, offer advantages of light weight, low cost, and ease of fabrication. Other dominant members in this class are polyamides, modified polyphenylene oxide, acetal, and polyester. This article looks at the properties of PCs, at the uses these properties engender, and finally at the chemistry used to generate these properties. 39 refs

Sikdar, Subhas K. *CHEMTECH v 17 n 2 Feb 1987 p 112-118.*

**081197 PHENYLENE MOTION IN POLYCARBONATE AND POLYCARBONATE/ADDITIVE MIXTURES.** Pulsed deuteron NMR line shapes have been analyzed to characterize type and time scale of the phenylene group motion in glassy bisphenol-A polycarbonate. The motional mechanism involves  $\pi$ -flips about the  $C_1C_4$  axis augmented by small angle fluctuations about the same axis, reaching a rms amplitude of  $\pm 35^\circ$  at 380 K. The distribution of correlation times for the  $\pi$ -flips is heterogeneous in nature and can be described either by a log-Gaussian or an asymmetric distribution with a more rapid decay at high correlation times comparable to the Williams-Watts distribution. From both distributions essentially the same mean activation energy of 37 kJ/mol is obtained, whereas the temperature dependence width of the highly asymmetric distribution is somewhat smaller compared to the log-Gaussian distribution. The results of this work strongly suggest that the secondary mechanical relaxation and the large amplitude motions of the phenylene groups in polycarbonate are related. (Edited author abstract) 16 refs.

## Polymerization

**081199 DEVELOPMENT STUDY OF POLYCARBONATE REACTORS II. SCALE-UP AND DESIGN OF CONTINUOUS REACTORS.** For the polymerization process controlled by mass transfer in the production of polycarbonate, the performance of continuous operations by using 4 cascades of stirred tanks and a premixing tank has been studied. It was proposed that the uniform dispersion and constant size distribution of liquid drops can be considered as the scale-up criteria. Experimental

results showed that the molecular weight of polymers can be well controlled by using these principles. (Edited author abstract) 8 refs. In Chinese.

## Solutions

**081200 SOLUTION PROPERTIES OF POLY(THIOCARBONATES).** Poly(thiocarbonates) with alkyl side chains have been prepared, and the solution properties of these polymers were studied in different solvents. Comparison with other poly(thiocarbonate) analogs and poly(carbonates) shows that the conformational parameter ( $K_\theta$ ) and rigidity factor increase as the volume of the side chain increases. The effect of the side-chain structure on the solution properties is analyzed. (Author abstract) 20 refs.

Gargallo, Ligia (Pontifica Univ Catolica de Chile, Santiago, Chile); Soto, Elia; Tagle, Luis H.; Radic, Deodato. *J Appl Polym Sci* v 35 n 4 Mar 1988 p 1103-1113.

## Spectroscopic Analysis

**081201 SOLID STATE DYNAMICS OF GLASSY POLYCARBONATE-DILUENT SYSTEMS.** The molecular origin of relaxations in glassy polymers remains a subject of considerable discussion. In this work, the sub- $T_g$  motions in bisphenol-A polycarbonate (BPAPC) are investigated with the aid of high-resolution solid state carbon-13 nuclear magnetic resonance (NMR) spectroscopy. The NMR results are correlated with those from dynamic mechanical and dielectric spectroscopies. The multi-technique approach to characterize the solid state dynamics of BPAPC-diluent blends verifies the cooperative nature of micro-Brownian chain motions. (Edited author abstract) 27 refs.

Belfiore, Laurence A. (Colorado State Univ, Fort Collins, CO, USA). *J Elastomers Plast* v 19 n 4 Oct 1987 p 238-251.

**081202 <sup>2</sup>NMR ANALYSIS OF THE MOLECULAR ORIGIN OF THE THERMAL RELAXATIONS IN POLYCARBONATES.** <sup>2</sup>H NMR spectroscopy has been utilized to characterize the molecular dynamics associated with the thermal relaxations in amorphous polycarbonate materials. The methyl and phenyl groups of bisphenol A polycarbonate (BPAPC) and poly(ester carbonates) derived from BPA and tere- or isophthalic acid were independently deuterium labeled so as to characterize the molecular dynamics of each group as a function of temperature. The phenyl motions of both the BPA and terephthalate units were characteristic of 180° ring flips and large angle rocking motions. These motions ceased (relative to 100 KHz) between 40 and -30°C. The terephthalate phenyls were more motionally restricted at temperatures between -30 and 120°C than the BPA phenyls. (Edited author abstract). 12 Refs.

Smith, P.B. (Dow Chemical Co, Midland, MI, USA); Bubeck, R.A.; Bales, S.E. *Macromolecules* v 21 n 7 Jul 1988 p 2058-2063.

## Stability

**081203 POLYCARBONATES (PC).** As amorphous material PC is characterized by a high transmission, high deflection temperature under load (135 to 145°C) high toughness, high dimensional stability and electrical insulation resistance and, as reinforced product, by its stiffness with an even higher dimensional stability. By the addition of fire retardants PCs are resistant to ignition sources of various kind. The curve of the shear modulus versus temperature shows a distinct decrease only above 140°C. The high purity and the negligible migration of additives and colorants lead to a wide range of application in the food packaging sector and in medical technique. For unreinforced thermoplastics the creep modulus is unusually high. Existing or generated stresses are therefore only very slowly reduced by creeping, as compared with other

plastics. Due to the excellent balance of its properties and acceptable expenses, PC offers a wide and steadily growing range of applications. The world production capacity of PC is estimated to be 420000 to 440000 t/a. 10 refs.

Kirchner, K. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 35-37.

**081204 SHRINKAGE AND RELATED RELAXATION OF INTERNAL STRESSES IN ORIENTED GLASSY POLYMERS.** Stability of oriented glassy polycarbonate and poly(ethylene terephthalate) subjected to physical aging has been investigated in terms of shrinkage forces measurements. It was shown that the temperature and time dependent traces of shrinkage forces are very sensitive to the aging effects and when compared with the results of other experiments concerning instabilities of oriented polymers throw some light on the nature of internal stresses relaxation. Observed shrinkage behavior was qualitatively described on the basis of a multi-state mechanical model. (Edited author abstract) 19 refs.

## Structure See Also MONOMERS—Polymerization.

**081205 RING DYNAMICS IN A CRYSTALLINE ANALOGUE OF BISPHENOL-A POLYCARBONATE.** A polycarbonate has recently been reported. We prepared a deuterated form of this material in the hope that ring flipping could be detected in a system related to polycarbonate for which the molecular conformation and the packing structure are well established. Characterization of motion in the model system may help to differentiate between alternate schemes for motion in the polymer. It is found that at 350 K, most of the rings flip rapidly on the time scale set by the deuterium spectral width. The experimental spectrum was fit reasonably well with the assumption of a single rate constant for ring flipping of  $5.0 \times 10^6$  s<sup>-1</sup>, although the sharp edges of the spectrum signal that some rigid material remains even at the elevated temperature. The spectrum is best fit with a quadrupole coupling interaction slightly reduced in magnitude from that of the rigid crystal form. 6 refs.

## Synthesis

**081206 POLYMERIZATION BY PHASE TRANSFER CATALYSIS: 6. SYNTHESIS AND THERMAL DEGRADATION OF PHENOLPHTHALEIN POLYTHIOCARBONATE.** Phenolphthalein polythiocarbonate was obtained by phase transfer catalysis using several catalysts and characterized by inherent viscosity, i.e. spectroscopy, differential scanning calorimetry, and thermogravimetric analysis. From the thermogravimetric curve, the kinetics parameters were determined. Glass transition temperature, thermal decomposition temperature, activation energy, and preexponential factor were lower than those determined for the corresponding polycarbonate. (Author abstract) 12 refs.

Tagle, L.H. (Catholic Univ of Chile, Santiago, Chile); Diaz, F.R.; Valdebenito, N. *Polym Bull (Berlin)* v 18 n 6 Dec 1987 p 479-483.

**081207 POLYCARBONATES FROM CYCLIC CARBONATES, CARBANIONS, AND DIHALO COMPOUNDS.** A new route for the synthesis of polycarbonates in reactions of cyclic carbonates with potassium naphthalene and  $\alpha, \omega$ -dihalo compounds is presented. The mechanism of carbonate linkage formation involving 1,3-dioxolan-2-one ring opening is discussed. When oxiranes and CO<sub>2</sub> were used instead of cyclic carbonates a product containing inbuilt polyether segments of various lengths was formed. It was found that the reaction of 'living' polystyrene with cyclic carbonates and dihalo compounds gives products containing polystyrene blocks in the polymer chains. The effects of various agents activating carbonate anions on yield and molecular weight

of polycarbonates are examined. (Author abstract). 13 Refs.

## Testing See Also PLASTICS—Mechanical Properties; PLASTICS, REINFORCED—Failure.

**081208 FLEXED PLATE IMPACT TESTING V: INJECTION MOULDED POLYCARBONATE DISCS.** A program of impact tests on injection-molded edge gated discs of polycarbonate and on thinner discs derived by a machining operation have shown that the peak force is proportional to the specimen thickness, that a hole through the specimen at the point of impact reduces the strength by about 45% and that a sharp notch induces brittleness. The results are discussed in relation to the test method and in relation to the impact resistance of poly(ether sulphone). Experimental data also prove that a set of stress concentrators can be used in the flexed plate impact method to evaluate and compare materials systematically and to produce 'derating factors' for use in design. The consequential enhanced versatility of the test method has important implications for the future course of impact testing and for the translation of laboratory test data into predictions about serviceability. (Edited author abstract) 6 refs.

## Thermal Properties

**081209 MOTIONAL BEHAVIOR AND CORRELATION TIMES OF NITROXIDE SPIN PROBES IN POLYMERS ABOVE AND BELOW THE GLASS TRANSITION.** The reorientational motions of nitroxide spin probes have been investigated in several polymers above and below the glass transition temperature,  $T_g$ . Three amine-cured epoxy resins having differential cross-link densities and the thermoplastics bisphenol A polycarbonate and poly(dimethylphenylene oxide) were studied. At sub- $T_g$  temperatures from 100 to 300 K the reorientational correlation times were the same for two small spherical probes and one large cylindrical probe in all the epoxy systems. Below  $T_g$  the activation energies for the nitroxide correlation times were typically -11 kJ/mol, whereas above  $T_g$  the corresponding value was 24 kJ/mol after a correction for temperature-dependent changes in free volume. (Edited author abstract) 27 refs.

## Welding See Also THERMOPLASTICS—Welding.

**081210 VIBRATION WELDING OF THERMOPLASTICS. PART III. STRENGTH OF POLYCARBONATE BUTT WELDS.** In vibration welding of thermoplastics, frictional work done by vibrating two parts under pressure, along their common interface, is used to generate heat to effect a weld. The main process parameters are the weld frequency, the amplitude of the vibratory motion, the weld pressure, and the weld time or weld penetration. The effects of these parameters on weld quality were systematically studied by butt-welding polycarbonate specimens under controlled conditions over a wide range of process parameters, and then determining the strengths and ductilities of these welds by tensile tests. A significant result is the apparent existence of a weld-penetration threshold above which high weld strengths are attained, but below which the strength drops off. Under the right conditions, the strengths of polycarbonate butt welds are shown to equal the strength of the virgin polymer. (Edited author abstract). 5 Refs.

**081211 MANAGING PCB SPILLS.** To assist utilities in their efforts to deal with PCBs, three Electric Power Research Institute (EPRI) divisions are sponsoring a wide range of projects. Studies sponsored by the Environmental Control Systems (ECS) Department have addressed PCB spill assessment and remediation. Early work resulted in development of a commercially available portable analyzer capable of identifying the type and concentration of PCBs at a spill site. More recently, efforts have focused on investigating PCB migration in soils to help utilities determine appropriate spill response times, and on investigating and evaluating cleanup technologies for PCB spills on soils and porous surfaces (e.g., asphalt, concrete, and brick). This article discusses such cleanup technologies as in-situ vitrification, soil washing, and mechanical removal.

## Accident Prevention

**081212 LES MESURES DE PREVENTION CONTRE LES RISQUES DES PCB.** [Preventive Measures Against PCB Risks]. The harmful effects of PCB's can appear as a result of direct contact by individuals, dispersion in the environment or thermal decomposition. The preventive measures must take into account these three situations. Electrical protection of equipment is important in preventing PCB leakage and thermal decomposition. Fire fighting should allow for the possibility of energization. (Author abstract) In French. 6 refs.

Beau, Philippe (Electricite de France, Fr); Boyer, Michel; Gain, Emile. *RGE Rev Gen Electr n 8 Sep 1987 p 63-66.*

## Accidents

**081213 LA DECONTAMINATION DES SITES ET DES LOCAUX.** [Decontamination of Sites and Premises]. The decontamination of premises following an accident involving PCB's is a difficult operation calling for very careful preparation in order to specify correctly the work to be performed. Such work might call for diversified techniques of which several, according to the situation, might be applied simultaneously or one after another. Especially after a hot pollution situation, numerous precautions must be taken for the protection of the site and staff: above all, the contaminated areas must be isolated, access checked and air movements channelled. The sanction of work after checking and reception is the declassification process which signifies that the site is no longer considered to be dangerous. (Author abstract) In French.

Faisantieu, Daniel (PECSIE, Fr); Lalueque, Didier. *RGE Rev Gen Electr n 8 Sep 1987 p 71-77.*

## Applications

**081214 PCB: LEURS PROPRIETES ET LEURS APPLICATIONS DANS L'ELECTRONIQUE.** [PCBs: Their Properties and Applications in Electrical Engineering]. The polychlorobiphenyls or PCB's have been in industrial production since 1930. Their remarkable properties, especially their chemical stability and non-inflammability, have led to their utilization in numerous industries. After having reviewed the foregoing, the author offers an analysis more particularly as regards the situation in electrical engineering. (Author abstract) In French. 17 refs.

Gervason, Pierre (PRODELEC, Fr). *RGE Rev Gen Electr n 8 Sep 1987 p 5-11.*

## Chemical Analysis

**081215 L'ANALYSE DES PCB DANS L'INDUSTRIE ELECTRIQUE.** [PCB Analysis in the Electrical Industry]. The application of regulations often imposes the identification and titration of PCB's in dielectric fluids,

in various materials and in the environment. There are several methods present - essentially colorimetry and gaseous phase chromatography - but each one has its application field as well as its limits. Although analyses are currently carried out, difficulties exist, notably due to the fact that standardization is insufficient. (Author abstract) In French. 2 refs.

Carballeira, May (Lab Central des Industries Electriques, Fr); Gal, Jean-Yves. *RGE Rev Gen Electr n 8 Sep 1987 p 39-45.*

**081216 DETERMINATION OF BYPRODUCT POLYCHLOROBIPHENYLS IN COMMERCIAL PRODUCTS AND WASTES BY HIGH-RESOLUTION GAS CHROMATOGRAPHY/ELECTRON IMPACT MASS SPECTROMETRY.** A gas chromatography/electron impact mass spectrometry (GC/EIMS) method for the determination of byproduct polychlorobiphenyls (PCBs) measures the recovery of four <sup>13</sup>C-labeled PCBs to assure adequate recovery of the native PCBs from diverse matrices. Byproduct (i.e., non-Aroclor) PCBs differ from most other PCB mixtures in that no recognizable chromatographic pattern can be anticipated. In addition, many matrices may contain similar chlorinated organics. Since diverse sample matrices must be analyzed, various appropriate extraction/cleanup techniques must be applied to each matrix. A set of four <sup>13</sup>C-labeled PCBs are employed as recovery surrogates. Additional aspects of the subject are discussed. (Edited author abstract) 31 refs.

Erickson, Mitchell D. (Midwest Research Inst, Kansas City, MO, USA); Stanley, John S.; Turman, J. Kay; Going, John E.; Redford, David P.; Heggem, Daniel T. *Environ Sci Technol v 22 n 1 Jan 1988 p 71-76.*

**081217 MULTILABORATORY STUDY OF AUTOMATED DETERMINATIONS OF POLYCHLORINATED BIPHENYLS AND CHLORINATED PESTICIDES IN WATER, SOIL, AND SEDIMENT BY GAS CHROMATOGRAPHY/MASS SPECTROMETRY.** Polychlorinated biphenyls (PCBs) and chlorinated pesticides were determined in two water, three soil, and two sediment samples by six laboratories that used uniform calibration solutions and analytical procedures. Target analytes were identified and measured with special software operating on minicomputers that controlled mass spectrometer operation. PCBs were determined by level of chlorination, not as Aroclor formulations. All samples, except one soil sample, were fortified with pesticides. Water samples were fortified with PCBs (mixtures of Aroclors), but solid samples were known to be environmentally contaminated with PCBs. Results obtained with four combinations of extraction and analyte enrichment procedures (cleanup) for solid samples were compared, but no combination could be selected as best for all five samples. Several factors affecting data quality were identified. (Author abstract) 6 refs.

## Chemical Reactions

**081218 OCTANOL-WATER PARTITION COEFFICIENTS OF POLYCHLORINATED BIPHENYL CONGENERS.** Octanol-water partition coefficients ( $K_{ow}$ ) for 13 polychlorinated biphenyl (PCB) congeners were accurately determined by the generator column technique. These values were used to confirm a highly significant linear relationship between  $\log K_{ow}$  and the logarithm of the relative retention time on a nonselective gas chromatographic stationary phase. The total surface areas (TSA) for all the PCB congeners were determined by assuming planar molecules, van de Waal's radii for component atoms, and appropriate values for solvent radius, bond angles, and distances. The TSA was highly significantly correlated with  $\log K_{ow}$  and the relationship used to calculate  $\log K_{ow}$  values for all the PCB congeners. Further development of these relationships gave an expression for aqueous solubility which can be used to calculate the solubility for those PCB's where

appropriate data are available. (Author abstract) 43 refs.

## Chemistry

**081219 EXPERIMENTALLY DETERMINED HENRY'S LAW CONSTANTS FOR 17 POLYCHLOROBIPHENYL CONGENERS.** Henry's law constants (HLCs) have been experimentally determined for 17 polychlorobiphenyl (PCB) congeners by a gas-purging technique, with results ranging from  $0.3 \times 10^{-4}$  to  $8.97 \times 10^{-4}$  atm·m<sup>3</sup>/mol and an average value of  $3.53 \times 10^{-4}$  atm·m<sup>3</sup>/mol for the congeners studied. The experimental results are in good agreement with previously published values. For the entire group of congeners studied, measured HLCs were not correlated with molecular weight but did appear directly related to chlorine substitution pattern. Increasing HLCs coincided with greater degrees of ortho-chlorine substitution within a molecular weight class. This trend may be useful to relate individual HLCs to chlorine substitution patterns for the remaining PCB congeners. (Author abstract) 30 refs.

## Chromatographic Analysis See Also LUBRICANTS—Additives.

**081220 SOLVENT REMOVAL/THERMAL DESORPTION (SRTD) FOR EXTRACT CONCENTRATION AND CAPILLARY COLUMN INJECTION.** Many solvent extracts must be concentrated prior to analysis. Both Kuderna-Danish (K-D) concentration and inert gas blowdown are commonly used. Significant losses often occur with the latter. Solvent removal/thermal desorption (SRTD) on a precolumn was investigated as an alternative or supplement to these methods. The compounds studied included polychlorinated biphenyls (PCBs) and polybrominated biphenyls (PBBs). The mean total recoveries and mean standard errors obtained were 109 and  $\pm 12\%$ , respectively. SRTD was found to give sharper peaks than were obtainable with on-column injection. (Edited author abstract) 39 refs.

**081221 ANALYSE DE PCB PAR CHROMATOGRAPHIE EN PHASE GAZEUSE.** [PCB Analysis by Gaseous Phase Chromatography]. Gaseous phase chromatography is certainly the best analysis method for PCB's. The article describes the equipment and operating modes used, and then specifies the conditions applicable to various cases that might be encountered, such as mixtures of PCB families, mineral oils and other insulating fluids, analysis in water, soils and other materials. (Author abstract) In French. 14 refs.

Grob, Robert (Ecole Natl Supérieure de Chimie de Toulouse, Fr). *RGE Rev Gen Electr n 8 Sep 1987 p 55-62.*

**081222 DETERMINATION OF POLYCHLORINATED BIPHENYLS IN SEDIMENT BY ON-LINE NARROW-BORE COLUMN LIQUID CHROMATOGRAPHY/CAPILLARY GAS CHROMATOGRAPHY.** Narrow-bore column liquid chromatography coupled on-line with capillary gas chromatography (LC/GC) is used for the determination of polychlorinated biphenyls (PCBs) in sediment via a heart-cutting technique. This method is compared with a method in which two off-line column clean-up steps are used with subsequent analysis by capillary gas chromatography. For the LC/GC analysis the recovery of PCBs was 90-100%.

For two sediment samples from the river Meuse the LC/GC and the other, more laborious method showed good agreement. (Author abstract) 17 refs.

## Cleaning

**081223 CONTROLLING SOLVENT LOSSES.** With the advent of legislation on their production and use, it is important that CFC-113 and other solvents used in PCB cleaning operations are handled in such a way as to minimise wastage. The author offers some guidelines to help users reduce emissions and operate their plants more economically. He discusses installation or movement of industrial cleaning equipment, storage and transfer of solvents, and operation of the cleaning plant. (Edited author abstract).

Campbell, Nick. *Electron Prod (London)* v 17 n 6 Jun 1988 p 48-49.

## Combustion

**081224 LA DESTRUCTION DES PCB: LE PROCEDE PAR INCINERATION.** [Destruction of PCBs: Incineration Process]. Destruction of PCB's or equipment comprising PCB's, without environmental pollution can be efficiently carried out by decontamination and incineration under proper conditions. The paper points out the parameters allowing a good incineration and describes TREDI company's facilities. (Edited author abstract) In French.

Milleret, Georges (TREDI). *RGE Rev Gen Electr* n 8 Sep 1987 p 151-155.

## Decomposition

**081225 EFFICIENCIES OF ALUMINUM, MAGNESIUM, AND THEIR OXIDES IN THE DESTRUCTION OF VAPOR-PHASE POLYCHLOROBIPHENYLS.** The destruction efficiencies of aluminum metal and oxide surfaces toward polychlorobiphenyls (PCBs) and related systems, including decachlorobiphenyl and hexachlorobenzene, have been measured from 500 to 800°C. Chlorocarbon destruction efficiencies > 99.99% were frequently obtained. The principal reaction products were aluminum chloride and carbonaceous char. It is proposed that metals showing the most effective dechlorination activities toward PCBs are those that have the highest standard heats of formation for the metal chlorides. (Edited author abstract) 7 refs.

## Decontamination

**081226 TECHNICAL/ECONOMIC ASSESSMENT OF SELECTED PCB DECONTAMINATION PROCESSES.** Eleven emerging alternative treatments for polychlorinated biphenyl (PCB) contaminated sediments have been compared and ranked using technical performance, status of development, test and evaluation data needs, and cost as factors. The emerging treatment processes are based on six different technologies: one on low-temperature oxidation, two on chlorine removal, one on pyrolysis, three on removing and concentrating, one on vitrification, and three on microorganisms. Types of technologies not developed are chlorinolysis, stabilizing, and enzymes. On the basis of the comparisons made, the treatment processes were ranked in the following order from highest to lowest: KPEG, LARC, Acurex, Bio-Clean, Supercritical Water, Advanced Electric Reactor, Vitrification, OHM Extraction, Soilex, Composting, and Dybron Bi-Chem 1006. (Edited author abstract) 88 refs.

*Mater* v 17 n 2 Feb 1988 p 125-148.

## Degradation

**081227 ZUR ENTGIFTUNG VON POLYCHLORIRERTEN BIPHENYLEN UND DIBENZODIOXINEN - EINE UBERSICHT.** [Detoxification of Polychlorinated Biphenyls and Dibenzodioxins - A Review]. A review is given on the state of the art for the destruction and detoxification of polychlorinated biphenyls (PCB) and polychlorinated dibenzo-p-dioxins (PCDD) including thermal and chemical techniques, photolytic, radiolytic and catalytic processes, destruction in supercritical fluids, and biochemical degradation. (Edited author abstract) In German. 71 refs.

Martinetz, Dieter (Akad der Wissenschaften der DDR, Leipzig, East Ger). *Chem Tech (Leipzig)* v 39 n 11 Nov 1987 p 466-470.

## Dehalogenation

**081228 BOROHYDRIDE, MICELLAR, AND EXCIPIEX-ENHANCED DECHLORINATION OF CHLOROBIPHENYLS.** The photodechlorination of polychlorinated biphenyls (PCBs) has been studied in the presence of sodium borohydride, detergents, and excipient-forming additives. In a family of 13 representative PCBs these variations generally led to a dramatically increased rate of photodegradation. Further, the products of photoreaction in the presence of sodium borohydride are more cleanly the simple dechlorinated aromatics, with fewer side reactions than observed with ordinary photolysis. (Author abstract). 32 Refs.

Epling, Gary A. (Univ of Connecticut, Storrs, CT, USA); Florio, Emily M.; Bourque, Andre J.; Qian, Xhi-Hong; Stuart, James D. *Environ Sci Technol* v 22 n 8 Aug 1988 p 952-956.

**081229 DEGRADATION AND DEHALOGENATION OF POLYCHLOROBIPHENYLS AND HALOGENATED AROMATIC MOLECULES BY SUPER-OXIDE ION AND BY ELECTROLYTIC REDUCTION.** Polyhalogenated aromatic hydrocarbons (e.g., PCB's and hexachlorobenzene) are rapidly degraded by superoxide ion in dimethylformamide to carbonate and halide ions. The efficient destruction of such materials is accomplished via the in situ electrolytic reduction of dissolved oxygen to generate superoxide ion, which reacts with polyhalo aromatics by nucleophilic substitution. The reaction stoichiometries have been determined by cyclic voltammetric measurements, and the reactant/product profiles have been assayed by capillary gas chromatography and potentiometric titrations. Study results are discussed. Electrochemical studies confirm that all PCB's can be dehalogenated via anaerobic electrolysis. (Edited author abstract). 24 Refs.

Environmental Impact See Also HYDROCARBONS—Environmental Impact.

**081230 L'EMPLOI DES PCB DANS LES TRANSFORMATEURS ELECTRIQUES PRESENTE-T-IL DES RISQUES?** [Are There Risks Involved in the Use of PCBs in Electric Transformers?]. By means of a historical review, the authors recount the problems raised by the operation of PCB transformers following the revelations in 1966 of environmental pollution by these compounds, and then the discovery of the presence of furans and dioxins in a building in Binghamton (1981). Basing themselves on an analysis of transformer failures occurring during operation, the authors examine the risks that the environment runs in the presence of furans and dioxins as well as those of the PCB's. The reader is reminded that such other furan and dioxine sources - as incinerators, herbicides, chlorophenols - and organo-chlorinated products comparable to the PCB's (DDT, di-

drine) represent ecological and public health problems that are far more worrisome than those arising from transformer operation. (Author abstract) In French. 66 refs.

**081231 COMPARISON OF SOME SPECIFIC POLYCHLORINATED BIPHENYL ISOMERS IN HUMAN AND MONKEY MILK.** This paper compares the relative amounts of 29 selected PCB isomers in human and monkey milk samples. The selection of isomers was based on the most prevalent PCB isomers in human milk as reported by S. Safe et al. and represented approximately 80% of all reported isomers. In addition, Aroclor 1254, whose toxicity in monkeys has been investigated recently by several investigators was analyzed for the same 29 selected PCB isomers. Study materials, methods and results are discussed. 11 refs.

Mes, Jos (Health & Welfare Canada, Ottawa, Ont, Can); Marchand, Lorrie. *Bull Environ Contam Toxicol* v 39 n 5 Nov 1987 p 736-742.

**081232 POLYCHLORINATED BIPHENYLS IN BLUE CRABS FROM SOUTH CALIFORNIA.** During the spring of 1985, commercial crab fishermen in Beaufort County, South Carolina contacted the South Carolina Wildlife and Marine Resources Department (SCWMD) concerning their perceptions of significantly declining catch rates. Using knowledge of previously documented elevated polychlorinated biphenyls (PCB) levels in the sediments of the upper portion of Campbell Creek the SCWMD initiated analysis of crab tissue from the area to ascertain the body burdens of PCBs. The subsequent work reported here was conducted between June and October 1985. The initial response by SCWMD to concerns of local commercial crabbers documented the presence of PCBs in the backfin tissue of crabs from the Campbell Creek area. The expanded sampling effort indicated that the PCB contamination of crab tissue was a near-field effect in Campbell Creek related to the off-marsh industrial facility operations. Additional aspects of the study are discussed. 10 refs.

**081233 PCB CONCENTRATIONS IN WINTER FLOUNDER FROM LONG ISLAND SOUND, 1984-1986.** PCBs (polychlorinated biphenyls) pollutants of concern in Long Island Sound have been studied previously. Initial studies at this laboratory focused on levels of PCBs and metals in tissues from windowpane flounder (*Scophthalmus aquosus*) collected from various stations in the Sound. In the present study, winter flounder (*Pseudopleuronectes americanus*) were collected from several stations in Long Island Sound and the gonads and livers analyzed for PCBs. Winter flounder were selected because they are both commercially and recreationally important in northeast Atlantic waters, including Long Island Sound. Study materials, methods and results are discussed. 8 refs.

Greig, Richard A. (Natl Marine Fisheries Service, Milford, CT, USA); Sennfelder, George. *Bull Environ Contam Toxicol* v 39 n 5 Nov 1987 p 863-868.

**081234 PCB PROBLEMS IN THE FUTURE: FORESIGHT FROM CURRENT KNOWLEDGE.** From a global point of view, PCB levels in the environmental media and biota are unlikely to decline in the near future due to the greater quantities of PCBs still in use than the quantity that has already escaped into the open environment. Considering all the information on the occurrence, distribution and behaviour of PCBs in the ecosystems, the marine mammals are probably the most vulnerable and possible target organisms in forthcoming long-term PCB toxicity. The recent isomer-specific analy-

ses suggest that the intrinsic toxicity of PCBs principally resulted from the coplanar PCB congeners which may impose a greater toxic threat than chlorinated dioxins and furans to humans and wildlife. (Edited author abstract) 130 refs.

Tanabe, Shinsuke (Ehime Univ, Matsuyama, Jpn). *Environ Pollut* 1987 v 50 n 1-2 1988 p 5-28.

**081235 PCBs IN THE ENVIRONMENT.** Polychlorinated biphenyls (PCBs) were extensively used in electrical equipment as lubricants, coolants and as fireproofing agents until their toxicity and persistence were recognised in 1966. PCBs are no longer manufactured in the UK but we have a legacy of production and other wastes. This article describes the first attempt to assess the scale of UK environmental pollution by PCBs. (Author abstract) 28 refs.

Edujee, G.H. (Environmental Resources Ltd, London, Engl). *Chem Br* v 24 n 3 Mar 1988 p 241, 243-244.

**081236 POLYCHLORINATED BIPHENYLS IN FISH-EATING SEA BIRDS - MOLECULAR FEATURES AND METABOLIC INTERPRETATIONS.** Residue analysis of the adipose tissue of five species of fish-eating sea birds from British and Irish coastal waters revealed the presence of up to 60 different congeners. It was possible to identify and quantify 40 different congeners. Despite the large number of PCB congeners identified only 10 accounted for >80% of the total PCBs. A PCB congener was identified accounting for 5% of the total PCBs (2,3',4,4',5',6-hexachlorobiphenyl) not usually reported in biological samples. Comparison of the molecular structure for the persistent PCB congeners revealed the lack of meta-para unsubstituted adjacent carbon atoms. It has been shown that meta-para unsubstituted adjacent carbon atoms facilitate the metabolism of PCBs and it is hypothesised that the formation of hydroxy derivatives may depend upon such a requirement. (Edited author abstract) 9 refs.

## Environmental Testing

**081237 DISPOSITION OF TOXIC PCB CONGENERS IN SNAPPING TURTLE EGGS: EXPRESSED AS TOXIC EQUIVALENTS OF TCDD.** Toxicological studies have demonstrated that the most toxic PCB congeners, isosteromers of tetrachlorodibenzo-p-dioxin (TCDD), require no metabolic activation. The structures of PCB congeners and isomers which favor induction of cytochrome P-448 are also those which are toxic and resist metabolism. These compounds possess a minimum of four chlorine atoms and therefore highly lipophilic. This paper reports on a study to determine if the heavy fat bodies of the female turtle provide a sufficiently large sink to retain the toxic congeners and prevent their incorporation into the eggs. Study materials, methods and results are discussed. 13 refs.

Bryan, A.M. (State Univ of New York at Albany, Albany, NY, USA); Stone, W.B.; Olafsson, P.G. *Bull Environ Contam Toxicol* v 39 n 5 Nov 1987 p 791-796.

**081238 DEPOSITION AND EVAPORATION OF POLYCHLOROBIPHENYL CONGENERS TO AND FROM SISKIWIIT LAKE, ISLE ROYALE, LAKE SUPERIOR.** The relative importance of polychlorobiphenyl (PCB) transport into and out of lakes was studied by constructing a mass balance of PCB congeners in Siskiwit Lake, a remote lake in the Isle Royale National Park in Lake Superior. Measurements of winter and summer air, rain, snow, water, and sediments were obtained over several months and used to determine PCB fluxes to and from the lake, assuming steady-state conditions over 1 year. By solving the mass balance equation under selected conditions, we estimated the deposition velocity and the overall liquid water-to-air mass transfer coefficient for PCBs to be 0.16 cm/s and 0.1 m/day,

respectively. Wet deposition was generally 3 times as great as dry deposition and was dominated by particle washout. Removal from the lake by volatilization was more important than sedimentation for most congeners. (Author abstract) 62 refs.

## Fires

**081239 PCBs IN ELECTRICAL EQUIPMENT - A GROWING CONCERN.** Polychlorinated biphenyls, better known as PCBs, have been widely used in power distribution systems and electrical equipment. They are part of the family of synthetically manufactured organic chemicals known as chlorinated hydrocarbons. They were once prized for their stability and fire resistance before it was discovered that when PCBs are exposed to heat or flames producing temperatures ranging from 570 to 1100 degrees Fahrenheit (and some scientists report at temperatures at or below 300 degrees F.) they form extremely toxic substances. Electrical equipment containing 50 parts per million (ppm) or greater of PCBs located in or near a facility can pose a serious risk to that facility, and its occupants in the event they become involved in a fire. 24 refs.

Alderman, Forrest R. *Prof Saf* v 32 n 5 May 1987 p 13-16.

## Legislation

**081240 LA REGLEMENTATION DES PCB. [PCB Regulations].** Over the past twelve years or so, more than twenty legislative and regulatory texts, as much European as French have been published on PCB's. Essentially, the texts are intended for the prevention of accidents and to limit consequences thereof - this includes management and destruction of wastes - as well as protection of the workers. This article contains an analysis of these texts or at least their principal provisions. These are presented in resume form in a table appearing in the appendix. (Author abstract) In French. 21 refs.

Delpirou, Dominique (Electricite de France, Fr); Coin, Remy. *RGE Rev Gen Electr* n 8 Sep 1987 p 79-82.

## Manufacture

**081241 ADDITIVE LEITERPLATTENHERSTELLUNG. [Manufacturing PCBs by the Additive Process].** Starting point for manufacturing PCBs by the additive process are base materials coated with bonding agents, viz. phenol resin paper laminates, epoxy resin laminates. They are similar to those used for the subtractive system, except that the laminates are not coated with copper but with a bonding agent. Details of the process are explained by drawing comparison with the semiadditive system. (Author abstract) In German. 5 refs.

Steffen, H. *F&M Feinwerktech Messtech* v 96 n 3 Mar 1988 p 95-97.

## Oxidation

**081242 CATALYTIC OXIDATION OF POLYCHLORINATED BIPHENYLS IN A MONOLITHIC REACTOR SYSTEM.** Air containing 200-1000 ppm of Aroclor 1254 vapors [a mixture of polychlorinated biphenyls (PCBs)] was passed through a 22.86 cm long heated section of 0.64 cm i.d. monolithic  $\alpha$ -alumina support, which had been previously treated with one or more catalytic agents. At 600°C, with a residence time of about 9.4 s, results showed that the overall PCB destruction efficiency ranged from a high of 97.3% for supported CuO to a low of 69.3% for Cr<sub>2</sub>O<sub>3</sub>. Supported catalysts of Co<sub>3</sub>O<sub>4</sub>, CuCr<sub>2</sub>O<sub>4</sub>, and Pt-Pd were intermediate in activity. Relative activity for this group of p-type catalysts in deep oxidation was in accordance with Sabatier's principle, decreasing with increasing heats of O<sub>2</sub> chemisorption. Selectivity toward oxidation of the more toxic high-chlorine-containing PCBs was found to be greater for catalysts made from transition metal oxides than for noble metal

systems or homogeneous (thermal) decomposition. (Author abstract) 15 refs.

Subbanna, Prasad (Univ of Akron, Akron, OH, USA); Greene, Howard; Desai, Fareedoon. *Environ Sci Technol* v 22 n 5 May 1988 p 557-561.

## Solubility

**081243 AQUEOUS SOLUBILITY OF POLYCHLORINATED BIPHENYLS RELATED TO MOLECULAR STRUCTURE.** Aqueous solutions of polychlorinated biphenyls show a linear relationship between logarithms of aqueous activity coefficients and total surface areas (TSA) or total molecular volumes (TMV). The aqueous activity coefficients were calculated from experimental solubility data and values taken from the literature. The correlations improved substantially if a differential heat capacity between supercooled liquid and solid chemical equal to the entropy of fusion was assumed. In addition, it was found that dissolution of 2,2',4,4'-tetra- and 2,2',4,4',5,5'-hexachlorobiphenyl was accompanied by positive enthalpy and entropy changes, the entropy being dominant at room temperature. Additional study results are discussed. (Edited author abstract) 65 refs.

Oppehuizen, Antoon (Univ of Amsterdam, Amsterdam, Neth); Gobas, Frank A.P.C.; Van der Steen, Jan M.D.; Hutzinger, Otto. *Environ Sci Technol* v 22 n 6 Jun 1988 p 638-646.

## Sorption

**081244 SORPTION AND DESORPTION DYNAMICS OF AROCLOR 1242 TO NATURAL SEDIMENT.** Sediment sorption and desorption processes are important in determining the movement and fate of persistent organic compounds in aquatic systems. Batch experiments show that after an initial one week uptake period, continual release of Aroclor 1242 from sediment occurs over a six-month period. These observations suggest that a two-stage kinetic model, rather than the conventional equilibrium model, is more appropriate for representing sediment uptake and release processes. Additional batch studies were used to measure short- and long-term rate coefficients for these processes. Simulation studies, with multiple sediment and contaminant inputs, indicate that over a 16-day period a kinetic model better matches the experimental data than do three other equilibrium-based sorption/desorption models. (Edited author abstract). 50 Refs.

Witkowski, Patrick (Princeton Univ, Princeton, NJ, USA); Jaffe, Peter; Ferrara, Raymond. *J Contam Hydrol* v 2 n 3 Jul 1988 p 249-269.

## Spectroscopic Analysis

**081245 DIRECT QUANTITATION OF PCB CONGENERS USING A HELIUM DISCHARGE DETECTOR AND INTERNAL STANDARD TECHNIQUES.** Individual PCB congeners have been quantitated at ppm levels, with an average error of  $\pm 3.2\%$ , with the use of a helium discharge detector (HDD) for element-selective detection of Cl emission. Chlorinated internal standards of known concentrations were added to each solution determined to establish the relative peak areas per unit concentration of Cl present. No detector precalibration or response factor formulations were required, since the detector response is based solely on the moles of Cl present. The same methodology was utilized to determine the % Cl in Aroclor samples without prior identification of the PCB congeners present. (Author abstract) 18 refs.

McAteer, Peter J. (Coll of William & Mary, Williamsburg, VA, USA); Ryerson, Tom B.; Argentine, Mark D.; Ware, Margaret L.; Rice, Gary W. *Appl Spectrosc* v 42 n 4 May-Jun 1988 p 586-588.

**Toxicity** See Also INSULATING OIL—Oxidation; LIQUIDS—Dielectric Properties.

**081246 HIGHLY TOXIC COPLANAR PCBs: OCCURRENCE, SOURCE, PERSISTENCY AND**

**TOXIC IMPLICATIONS TO WILDLIFE AND HUMANS.** Isomer-specific determinations of PCB congeners in a wide variety of animal species such as fish, marine mammals (whale, dolphin and porpoise) and terrestrial mammals (dog, cat and human) revealed the environmental occurrence of highly toxic coplanar 3,3',4,4'-tetrachlorobiphenyl (T<sub>4</sub>CB), 3,3',4,4', 5-pentachlorobiphenyl (P<sub>5</sub>CB) and 3,3',4,4',5,5'-hexachlorobiphenyl (H<sub>6</sub>CB) within a range of few pg g<sup>-1</sup> to several ten ng g<sup>-1</sup> in fat tissues (except fish) on a wet weight basis. The sources of coplanar PCB contamination to the environment are mainly commercial PCB preparations. Marine mammals seem to have lower potency to metabolize the coplanar PCBs in comparison with terrestrial mammals. In human adipose tissues, the concentrations of coplanar PCBs were found to be much higher than 2,3,7,8-tetrachlorodibenzo-p-dioxin (T<sub>4</sub>CDD), 2,3,4,7,8-pentachlorodibenzofuran (P<sub>5</sub>CDF) and other toxic congeners. 'T<sub>4</sub>CDD-equivalent' analysis based on the enzyme induction potencies and the residues of these toxic chemicals indicates that 3,3',4,4',5-P<sub>5</sub>CB may impose a greater toxic threat than dioxins and furans to the humans and probably to wildlife also. (Edited author abstract) 31 refs.

Tanabe, S. (Ehime Univ, Matsuyama, Jpn); Kannan, N.; Subramanian, A.; Watanabe, S.; Tatsukawa, R. *Environ Pollut* (1987) v 47 n 2 1987 p 147-163.

**081247 LES PCB ET LEURS PRODUITS DE DECOMPOSITION — THERMIQUE: PEUT-ON EVALUER UN SEUIL DE TOXICITE? [Can a Toxicity Threshold be Assessed for PCBs and Their Decomposition Products?].** After offering an account of the experimental toxicological properties of PCBs, polychlorobiphenyls (PCB), polychlorodibenzodioxins (PCDD) and polychlorodibenzofurans (PCDF), the author takes up the problem of extrapolation to man of the experimental results obtained on animals. The large number of isomers, displaying highly-different toxicological intensities, and the large dispersion of the sensitivities of the animals tested render uncertain a quantitative assessment of toxic risk for man, especially as regards PCDD's and PCDF's. (Author abstract) In French. 40 refs.

Millischer, Rene-Jean (Toxicologie Industrielle, Fr). *RGE Rev Gen Electr* n 8 Sep 1987 p 23-37.

**081248 SURVEILLANCE MEDICALE DES TRAVAILLEURS EXPOSES AUX PCB.** [Medical Surveillance of Workers Exposed to PCBs]. Medical surveillance is indispensable for workers likely to be exposed professionally to PCB's or their deterioration products due to these workers' daily activities or as a result of accidents. Such surveillance consists, first, of removal from exposed employment of those individuals who display certain counter-indications and then the conduct of periodical visits and examinations of various nature. (Author abstract) 4 refs.

Folliot, Dominique (EDF, Fr). *RGE Rev Gen Electr* n 8 Sep 1987 p 68-69.

**081249 TOXIC EFFECTS OF PCBs AND RELATED COMPOUNDS IN HUMANS AND ANIMALS.** For the general public, the expression PCBs is synonymous with danger. Given their persistence in the environment and in living organisms, people fear their effects on health and more specifically their consequences for reproduction and breast-fed babies, and their carcinogenic effects. The greatest health risk is fire in equipment insulated with PCBs, incomplete combustion of which leads to the formation of substances deemed to be extremely toxic, primarily furans and, where there is an associated solvent (polychlorobenzene), dioxins. In light of documentation available on PCBs, their contaminants and combustion products, this article attempts to answer a number of questions about the persistence of these products in the environment and their toxicity for humans. (Edited author abstract)

Carrier, G. (Maisonnette-Rosemont Hospital, Montreal, Que, Can). *Pulp Pap Can* v 88 n 10 Oct 1987 p 79-82.

**081250 POLYCHLORINATED BIPHENYLS: A TOXICOLOGICAL REVIEW.** This report discusses the chemical and physical properties of PCBs, their biological disposition, and their reported toxicologic effects including carcinogenic potential. Specific comparisons are made between toxicity of PCBs in animals with effects observed in humans following exposure. Other areas covered include governmental regulation and permissible levels of exposure. Indeed, as a result of passage of the Toxic Substances Control Act in 1976, Congress singled out PCBs for regulation as required by law and the U.S. EPA banned further production in 1979. It is concluded that there are significant adverse effects of PCBs when administered to animals under laboratory conditions. However, with the exception of the development of chloracne, there is little evidence suggesting significant toxicity to man including carcinogenic effects resulting from the chronic exposure to PCBs in the workplace or environment. (Edited author abstract) 120 refs.

## Trace Analysis

**081251 DETERMINATION OF POLYCHLORINATED BIPHENYLS IN HUMAN FOODSTUFFS AND TISSUES: SUGGESTIONS FOR A SELECTIVE CONGENER ANALYTICAL APPROACH.** Based on a literature review of the occurrence of polychlorinated biphenyl (PCB) congeners in commercial formulations, environmental and biological samples and human tissues, and a consideration of the relative toxicity and persistence of the congeners, suggestions are made as to the most relevant components to be quantified by a selective congener analytical approach to human foodstuffs and tissues. These criteria suggest congener numbers 28, 74, 77, 99, 105, 118, 126, 128, 138, 153, 156, 169, 170, 179 and 180 will give a measure of > 70% of the total PCB tissue burden in a sample and be of greatest toxicological significance. Additionally, congeners 8, 37, 44, 49, 52, 60, 66, 70, 82, 87, 101, 114, 158, 166, 183, 187 and 189 are considered because of their reported occurrence or toxicity. (Author abstract) 58 refs.

## Transportation

**081252 TRANSPORT OF POLYCHLORINATED BIPHENYLS (PCBs) IN FRESHWATER MESOCOSMS FROM SEDIMENT TO WATER AND AIR.** With sediment as a source the flux of PCBs to water and air was followed in mesocosms with and without fish for two vegetation seasons. The fish represented the largest lipid pool in the mesocosm, and their presence increased the flux of PCBs across the sediment/water interface. The flow of PCBs from sediment to water followed a seasonal pattern with higher rates during summer than in the winter. The rates were governed by the turbation activity of benthic invertebrates, the extent of gas production in the sediment, the amount and quality of the lipid pools in the water column, and the solubility of the PCBs. The greatest amount of PCBs among the lipid pools was found in the dissolved extractable lipids, which also showed the highest concentration of PCBs calculated on a lipid basis. After about 1.5 yr, > 90% of the PCBs added was still in the sediment. (Edited author abstract) 44 refs.

**POLYELECTROLYTES** See Also COLLOIDS—Flocculation; COLLOIDS—Glass; COLLOIDS—Structure; ELECTROLYTES—Materials; MONOMERS—Polymerization; POLYSTYRENES—Encapsulation; PROTEINS—Precipitation; SUSPENSIONS—Flocculation; WASTEWATER—Treatment; WATER TREATMENT—Flocculation.

**081254 ADIABATIC COMPRESSIBILITY AND APPARENT MOLAL VOLUME OF IONIC MONOMERS, POLYMERS, AND COPOLYMERS IN AQUEOUS AND NONAQUEOUS SOLUTIONS.** In this review we are primarily concerned with the use of apparent molal volume and apparent molal compressibility of polyelectrolytes along with their corresponding monomers in elucidating the ion-ion and ion-solvent interactions in aqueous and nonaqueous solutions. Though the main emphasis will be given to synthetic polyelectrolytes, the biochemical significant (natural) ones are not excluded. Most of the works on molal volumes and ultrasonic velocity measurements were confined to solutions of simple electrolytes. These works gave valuable information about the structure of solutions as well as about the fundamental properties of solutions. 80 refs.

**081255 ELECTROCHEMICAL MEASUREMENT OF TRANSFERENCE NUMBERS IN POLYMER ELECTROLYTES.** Electrochemical methods for the determination of transference numbers in polymer electrolytes are considered and a new technique which overcomes some of the problems associated with other methods in current use is described. Results are given of measurements of the transference numbers of lithium and trifluoromethanesulfonate ions in poly(ethylene oxide) at 90°C. A mean value of 0.46±0.02 is reported for lithium. (Author abstract) 17 refs.

**081256 NON-STOICHIOMETRIC POLYELECTROLYTE COMPLEXES OF POLYACRYLIC ACID AND CATIONIC SURFACTANTS.** The macromolecular reactions of cationic surfactants with polyacrylic acid have been studied. In acid media (pH 3) as a result of these reactions non-stoichiometric PECs of constant composition insoluble in aqueous media form. In neutral and weakly alkaline media (pH ≥ 7) where the polyacid units are heavily ionized both water-soluble non-stoichiometric and stoichiometric insoluble PECs may form. The conditions for the formation of water-soluble non-stoichiometric PECs as a function of the length of the non-polar radical of the SA molecule have been studied. It is shown that increase in the length of the non-polar radical reduces the values of the composition of the mixture for which soluble non-stoichiometric PECs form. (Edited author abstract) 12 refs.

**081257 PHOTO PHYSICAL PROPERTIES OF PYRENE COVALENTLY BOUND TO POLYELECTROLYTES.** Copolymers of methacrylic acid, acrylic acid, and poly(styrenesulfonate) have been prepared with small mole fractions of 1-vinylpyrene. The fluorescence properties and quenching efficiencies in water have been measured for high and low pH with methylviologen, sulfonated propylmethylviologen, and a neutral zwitterionic viologen. It has been found that static (or contact)

quenching plays a significant role. Formation of a pyrene-viologen charge-transfer complex was observed at high and low pH. Charge separation following redox quenching does not occur for the viologens, unlike the analogous vinylidiphenylanthracene polymers. The absence of charge separation is tentatively ascribed to the formation of a relatively tightly bound complex during the quenching event. (Author abstract) 17 refs.

Stramel, R.D. (Univ of Texas, Austin, TX, USA); Nguyen, Chinh; Webber, S.E.; Rodgers, M.A.J. *J Phys Chem* v 92 n 10 May 19 1988 p 2934-2938.

**081258 FREE ENERGY CHANGE IN HYDROPHOBIC INTERACTIONS INVOLVING A POLYELECTROLYTE AND RUTHENIUM TRIS(BIPYRIDINE). A PULSED LASER STUDY.** Comparison between the effects of inert salts on the distribution of  $\text{Ru}(\text{bpy})_3^{2+}$  ions around three negative polyelectrolytes, poly(styrenesulfonate) (PSS), poly(vinyl sulfate) (PVS), and poly(acrylate) (PAA), is reported. Much higher ion concentrations are required in order to remove  $\text{Ru}(\text{bpy})_3^{2+}$  from PSS, as compared to removal from a PVS or PAA. Attributing the difference between these systems to the effect of hydrophobic interactions in the PSS enables the calculation of the free energy change involved in the formation of  $\text{Ru}(\text{bpy})_3^{2+}$ -PSS. The results show a definite distinction between  $\text{Ru}(\text{bpy})_3^{2+}$  'inside' and 'outside' the polymer, with no exchange during the lifetime of the excited state of the ruthenium tris(bipyridine),  $\text{Ru}(\text{bpy})_3^{2+}$  found to be much higher than 2,3,7,8-tetrachlorodibenzo-p-dioxin ( $\text{T}_4\text{CDD}$ ), 2,3,4,7,8-pentachlorodibenzofuran ( $\text{P}_5\text{CDF}$ ) and other toxic congeners. ' $\text{T}_4\text{CDD}$ -equivalent' analysis based on the enzyme induction potencies and the residues of these toxic chemicals indicates that 3,3',4,4',5,5'- $\text{P}_6\text{CB}$  may impose a greater toxic threat than dioxins and furans to the humans and probably to wildlife also. (Edited author abstract) 31 refs. +. The  $\text{Ru}(\text{bpy})_3^{2+}$  ions are located more deeply 'inside' the PSS as compared with the PVS. (Author abstract) 23 refs.

**081259 POLYELECTROLYTE SOLUTIONS: EQUILIBRIUM CONFORMATIONS OF THE MICROSTRUCTURE WITHOUT AND WITH EXTERNAL FIELDS.** The work presents a thorough discussion of the stable equilibrium states of conformation and electric polarization which may be obtained, in dilute polyelectrolyte solutions, in the absence or presence of external forcing. In the absence of forcing it is shown, for various plausible forms of quadratic and higher-order energies, that only the fully isotropic, nonpolarized state is stable. When an electric field is applied, stable axisymmetric ellipsoidal conformations may exist with the electric polarization response colinear with both the applied field and the axis of conformation. The whole discussion is based on a previously developed continuum model of polyelectrolyte solutions where the conformation is governed by a thermodynamically admissible evolution equation that contains entropy-nonproducing contributions involving the strain rate of the flow. Only shear-like changes of conformations are considered in the present work. (Edited author abstract) 27 refs.

**081260 STUDY OF THE MICRO-ENVIRONMENT OF POLYELECTROLYTIC COMPLEXES OF SODIUM DODECYLSULPHATE IN AQUEOUS SOLUTIONS BY THE DYE SPECTRAL-SHIFT METHOD.** The dye-spectral shift method (using methyl orange) has been used to assess the micro-environment of polyelectrolytic complexes formed by sodium dodecylsulphate with a copolymer of N-vinylpyrrolidone and the iodethyrate of N,N-diethylamino-ethylmethacrylate. It has been established that, in aqueous solutions of the complexes, depending on the proportions of the components and the ionic strength, two types of ordered structures are formed, which are characterized by different degrees of hydrophobicity of the micro-environment. It has been established by viscometry that complexes with enhanced hydrophobicity of the micro-environment are characterized by smaller hydrodynamic dimensions. (Author abstract) 13 refs.

**081261 QUATERNARY AMMONIUM POLYELECTROLYTES. V. AMINATION STUDIES OF CHLOROMETHYLATED POLYSTYRENE WITH N,N-DIMETHYLALKYLAMINES.** The amination reactions of chloromethylated polystyrene with N,N-dimethyldecylamine, N,N-dimethyltetradecylamine, and N,N-dimethylhexadecylamine were studied. The physical properties, particularly the solubility properties of the resulting polymers, are influenced by the hydrophobic properties of the long alkyl chain on the  $\text{N}^+$  atoms. The main factor that influences the kinetics of the reactions is the polymer-solvent interaction parameter. (Author abstract) 12 refs.

**081262 SCALING LAWS AND THE EFFECTS OF CONCENTRATION POLARIZATION ON THE PERMEABILITY OF HYALURONIC ACID.** Investigators have modeled the hydraulic permeability of hyaluronic acid using a fiber matrix model such as developed by J. Happel. However, C.R. Ethier found that the concentration dependence of the sedimentation rate of hyaluronic acid is inconsistent with the predictions of the fiber matrix model and with perfusion measurements of the hydraulic permeability. These discrepancies are investigated and a tentative explanation provided. The discrepancy found between the predictions of the fiber matrix model and the results of perfusion studies may be due to concentration polarization. This process was modeled and examined experimentally. The experimental results are in qualitative agreement with the theory. (Edited author abstract) 21 refs.

**081263 ON THE CHARGE STOICHIOMETRY UPON ADSORPTION OF A CATIONIC POLYELECTROLYTE ON CELLULOSIC MATERIALS.** Adsorption isotherms and adsorption stoichiometry of a low-molecular-weight ( $M_w = 5.9 \cdot 10^3$ ) cationic polyelectrolyte, 3,6-ioneone (Polybrene), on cellulosic fibers were studied. The charge density of the fibers was varied by means of carboxymethylation. It is shown that the adsorption isotherms are of the high-affinity type with a pronounced plateau level. The charge of the polymer adsorbed at this plateau level provide a relatively good measure of the charge (in meq  $\text{g}^{-1}$ ) on both the fibers and the MFC, except for the unsubstituted fiber sample. (Edited author abstract) 17 refs.

**081264 EXCHANGE AND COMPETITIVE ADSORPTION OF POLYELECTROLYTES ON BARIUM SULPHATE.** The desorption of polyelectrolyte molecules adsorbed on barium sulphate in the presence of various displacing species is reported. When polyacrylate (PAA) was both the adsorbed and displacing species, no significant desorption occurred when the dispersion medium was water. However, significant desorption occurred in 0.1 mol  $\text{dm}^{-3}$  NaCl, but only when the displacing PAA had a higher molecular mass than that adsorbed. The simultaneous adsorption of PAA and polystyrene sulphate (PSS) is also reported as a function of the molecular

mass of the two species and at different relative concentrations. In  $\text{H}_2\text{O}$ , there was a critical ratio of the weight of barium sulphate to the volume of polymer solution below which there was no detectable adsorption of PSS. The amount of PSS excluded from the surface increased as the ratio of PAA to PSS concentrations increased. The results indicate that the diffusion rate of PAA is the dominating factor in determining the surface composition. This suggests that the PSS must require a significant time from first contact of the molecule to complete adsorption, and in this time, newly arriving PAA molecules displace the PSS. 13 refs.

**081266 EFFECT OF APPLIED POTENTIAL ON THE ELLIPSOMETRIC THICKNESS OF SODIUM POLY(STYRENESULFONATES) ADSORBED ON A PLATINUM SURFACE.** The thickness of a sodium poly(styrenesulfonate) (NaPSS) layer adsorbed on a platinum plate was measured by ellipsometry in aqueous NaCl solutions as a function of molecular weight, solvency, and applied potential. The applied potentials correspond to cathodic and anodic potential differences relative to the rest potential. At the negative potential differences, with an increase in potential difference the thickness of the adsorbed layer increases and its variation with the molecular weight decreases. (Edited author abstract) 22 refs.

**081267 ENHANCED POLYELECTROLYTE ADSORPTION.** The amounts of hydrolysed polyacrylamide adsorbed onto cationic polystyrene latex have been compared after achieving the same final conditions of the dispersion medium via different experimental routes. The configuration of the adsorbed polymer molecules, following the different procedures, has also been assessed. For example, adsorption from 0.5 mol  $\text{dm}^{-3}$  NaCl followed by redispersion in 0.002 mol  $\text{dm}^{-3}$  NaCl leads to significant enhancement in the amount adsorbed compared to direct adsorption from the latter medium. In addition, the configuration, as indicated by ESR spectral data, has a much greater proportion of segments in loops and tails following the indirect route. (Edited author abstract) 24 refs.

**081268 POLYELECTROLYTE INTERACTIONS AT THE HEMATITE/WATER INTERFACE. PART 1.** Displacement of adsorbed polyelectrolytes at the hematite/water interface is investigated as a function of molecular weight, ionic strength and order of addition using monodisperse polystyrenesulfonate (PSS) (MW 4600 and 1,200,000) as the polymer. At low ionic strength, 0.001 kmol  $\text{m}^{-3}$ , adsorption isotherms of single polymer was independent of molecular weight. At 1 kmol  $\text{m}^{-3}$

NaCl, adsorption increased significantly with molecular weight. Polydispersity effects were studied by examining adsorption of premixed monodisperse samples of two molecular weights, 4600 and 1,200,000, on hematite, and analyzing using size exclusion chromatography. (Edited author abstract). 12 Refs.

Ramachandran, R. (Columbia Univ, New York, NY, USA); Somasundaran, P. *Colloids Surf* v 32 n 3 pt 4 Jul 1988 p 307-317.

**081269 POLYELECTROLYTE INTERACTIONS AT THE HEMATITE/WATER INTERFACE. PART 2.** Interactions of anionic polyacrylamide (PAM, MW 3 to 5 million) and monodisperse polystyrenesulfonate (PSS, MW 4600 and 1,200,000) at the hematite/water interface are examined. At low ionic strength, PAM displaced adsorbed PSS (MW 4600), but could not displace adsorbed 1,200,000 PSS. Increasing the ionic strength led to enhanced displacement of 4600 PSS by PAM. The entropic driving force at high ionic strength was sufficient to overcome the salting-out forces that led to lower adsorption of PAM alone at 1 kmol m<sup>-3</sup>. PAM, due to its lower anionicity, was not as good a displacer of 4600 PSS as 1,200,000 PSS. (Author abstract). 4 Refs.

Ramachandran, R. (Columbia Univ, New York, NY, USA); Somasundaran, P. *Colloids Surf* v 32 n 3 pt 4 Jul 1988 p 319-329.

**081270 VARIATION OF ELLIPSOMETRIC ADSORBED POLYELECTROLYTE LAYER THICKNESS WITH POTENTIAL.** The ellipsometric thickness of sodium poly(styrene sulfonate) (NaPSS) layers adsorbed from aqueous NaCl solution onto a platinum plate was measured as a function of molecular weight and applied potential. A cathodic potential with respect to the rest potential was applied. At rest potential the ellipsometric thickness scales as M<sup>0.5</sup> and M<sup>0.4</sup> in theta and good solvents, respectively, and increases with increasing solvent power (decreasing ionic strength). The variation of the ellipsometric thickness with the molecular weight at applied potentials differs markedly from that without applied potential and becomes weaker with increasing applied potential. (Edited author abstract) 31 refs.

**081271 KINETICS OF ADSORPTION AND ION-EXCHANGE REACTIONS DURING ADSORPTION OF CATIONIC POLYELECTROLYTES ONTO CELLULOSIC FIBERS.** The kinetics and stoichiometry of adsorption of a cationic polyacrylamide (C-PAM) and a 3,6-ionene on a carboxymethylated bleached cellulose pulp were investigated. The initial rate of adsorption of C-PAM was very fast, and approximately 50% of the equilibrium adsorption level had already been reached within 10 s after polymer addition. The degree of ion exchange between the C-PAM and the anionic charged groups on the fiber was initially small, but increased substantially when the equilibrium polymer adsorption level was approached. As the amount of polymer added was increased, a lower stoichiometry was reached both after 10 s and after 30 min. (Edited author abstract) 3 refs.

**081272 POLYELECTROLYTES CONTAINING DIHYDRONICOTINAMIDE. III. FLUORESCENCE QUENCHING BY NICOTINAMIDE-CONTAINING**

**POLYMERS IN AQUEOUS SOLUTION.** Charge-transfer (CT) interaction of N-benzyl-1,4-dihydronicotinamide (BNAH) and poly(sodium styrene-p-sulfonate) containing 6 mol % of BNAH groups (PNAH) with several types of nicotinamide-containing polyelectrolytes in aqueous solution was investigated by fluorescence quenching. The experimental data were analyzed in terms of a kinetic model including both static and dynamic quenching. Hydrophobic association of BNAH with the polymers led to more effective quenching than the monomer [N-benzylnicotinamide (BNA)] system. Electrostatic attraction of PNAH and BNA also resulted in the remarkably large value of apparent quenching constant. (Edited author abstract) 29 refs.

**081273 INTERACTION OF FLUORESCENT SPERMINE DERIVATIVE WITH A NUCLEIC ACID POLYION.** The interaction of multivalent counterions with polyelectrolytes is investigated with a new probe prepared by reaction of spermine tetrachloride with 4-chloro-7-nitrobenz-2-oxa-1,3-diazole (NBD). The resulting conjugate, NBD-Sp, is a fluorescent trivalent ion at neutral pH. This species binds to poly(dG)-poly(dC) (PGC), a double-stranded synthetic polynucleotide, with a concomitant reduction in fluorescence yield. The isotherm for reduction of the fluorescence has been utilized to determine the binding constant. Electrophoretic light scattering has been used to measure the reduction of the charge density on the PGC molecule as the NBD-Sp condensed. Fluorescence photobleaching recovery (FPR) has been used to determine the tracer diffusion coefficients of the fluorescent NBD-Sp species in solution as a function of added PGC. The results are interpreted to determine the relative strength of the interaction between NBD-Sp and the mobility of the NBD-Sp ions that are not tightly bound to the PGC. For the latter data it is shown that the tracer diffusion coefficient approaches a limiting value one-third of the diffusion coefficient in the absence of the polyion, in agreement with a model that assumes restricted motion radial to the polyion and unhindered motion along the isopotential lines defined by the polyion backbone. **Concentration**

**081274 SOLUTION PROPERTIES OF POLYELECTROLYTES. III. EFFECT OF SODIUM POLYSTYRENE SULFONATE CONCENTRATION ON VISCOMETRIC AND SIZE EXCLUSION CHROMATOGRAPHIC BEHAVIOR AT DIFFERENT IONIC STRENGTHS.** The effect of sodium polystyrene sulfonate concentration on the shape of its molecules in aqueous solution at different NaNO<sub>3</sub> ionic strengths has been analyzed by viscometry and size-exclusion chromatography (SEC). An equation has been developed which predicts the intrinsic viscosity at finite concentration of both polyion ( $c_p$ ) and electrolyte ( $c_e$ ). The experimental results obtained by both techniques can be accounted for in terms of the theory. Several factors involved in the elution mechanism have been considered and the variation of the slopes of SEC calibration curves with  $c_p$  and  $c_e$  has been discussed in terms of polyion conformation changes. (Edited author abstract) 40 refs.

**Condensation Reactions**

**081275 NEW MODEL OF COUNTERION CONDENSATION IN POLYELECTROLYTE SOLUTIONS. I. COMPARISON WITH OTHER CONDENSATION THEORIES AND EXPERIMENTAL DATA ON COUNTERION ACTIVITY COEFFICIENTS.** A new model of counterion condensation (Intermediate Model, IMM) is proposed as a modification of a corrected previous model (CPM). The theoretical predictions of IMM and CPM for the degree of condensation,  $\theta$ , and the counterion activity coefficient,  $\gamma$ , are compared with those of Manning and Iwasa et al. It is found that  $\gamma$ 's in the absence of added salts estimated by IMM and CPM for infinitely long polyions are hardly dependent on the polymer concentration,  $C_p$ , while those for polyions with finite length increase with decreasing  $C_p$ . It is the latter that is experimentally observed. This fact indicates that polymer models, in which end effects are considered, should be employed to treat the dependence of the condensation phenomena on the ionic strength. (Edited author abstract) 35 refs.

Satoh, Mitsuru (Tokyo Inst of Technology, Tokyo, Jpn); Kawashima, Takehito; Komiya, Jiro; Iijima, Toshiro. *Polym J* v 19 n 10 1987 p 1191-1200.

**081276 NEW MODEL OF COUNTERION CONDENSATION IN POLYELECTROLYTE SOLUTIONS. II. APPLICATION TO POTENTIOMETRIC TITRATION OF WEAK POLYACIDS.** The apparent dissociation constants,  $pK_a$ , of weak polyacids in aqueous salt solutions are estimated as a function of the degree of dissociation,  $\alpha$ , by a new model for counterion condensation (Intermediate Model, IMM) and a corrected previous model (CPM). Both models predict smooth titration curves free from a break point which is a defect in the prediction by Manning theory. Titration curves obtained by CPM show a maximum, indicating that CPM overestimates the degree of condensation with increasing  $\alpha$ . Sigmoidal titration curves are predicted by IMM; the underestimation for a lower  $\alpha$  region of poly(acrylic acid) is corrected through effective charge densities estimated from the counterion activity data, and that observed for a higher  $\alpha$  region is interpreted as caused by hydration changes of the polyion with  $\alpha$ . (Edited author abstract) 24 refs.

**Diffusion**

**081277 EFFECTS OF POLYELECTROLYTES ON THE DIFFUSION OF LOW MOLECULAR WEIGHT IONIC SOLUTES.** The diffusion of sodium sulfate in dilute solutions of carboxymethylcellulose sodium salt (CMC) was studied using the porous frit technique. It was found that at relatively low CMC concentrations, the diffusivity of sodium sulfate (D) is higher than that in water ( $D_0$ ); with increasing CMC concentration, the diffusivity of sodium sulphate decreases gradually and reaches a value lower than that in water. The relation between salt diffusivity ratio ( $D/D_0$ ) and CMC concentration (C) is represented by the equation:  $D/D_0 \times a - bC$ . The effect of temperature on the diffusivity of sodium sulfate in CMC solutions was found to obey the Arrhenius equation with an activation energy of 2600 cal mol<sup>-1</sup>. (Author abstract) 16 refs.

**Dispersions**

**081278 DETERMINATION OF EFFECTIVE CHARGE NUMBERS OF A POLYDISPERSE POLYELECTROLYTE: AN IMPROVED METHOD.** An improved method for the determination of effective charge numbers of polydisperse polyelectrolyte is presented. Instead of an earlier used zero-flux condition we now solve the mathematical model of convective diffusion in the case of non-zero fluxes. This is done in a binary supporting

electrolyte system where the solution can be obtained in closed form. Even though the charge numbers have to be iterated from this closed form solution, it is reasonable to use the present method due to experimental reasons if the supporting electrolyte system is binary. The measurements for both the ionic diffusion coefficients and the effective charge numbers were done when the supporting electrolyte was 0.01 M NaCl and the polydisperse polyelectrolyte was lignosulfonate present in trace-ion concentration  $1 \text{ g dm}^{-3}$ . The results were in accordance with those obtained earlier. (Author abstract) 5 refs.

## Effects

**081279 EFFECT OF POLYELECTROLYTES ON THE ELECTROKINETIC POTENTIAL OF MELAMINE-FORMALDEHYDE PARTICLES.** It is shown that with an increase in the adsorption of sodium salts of carboxymethylcellulose (CMC) on the surface of oppositely charged melamine-formaldehyde particles there is a decrease in their  $\zeta$ -potential and a subsequent charge exchange, the efficiency of this decrease increasing with an increase in the molecular weight and charge of the macroion and with an increase in the radius of curvature of the adsorbing surface. A relationship is shown between the electrokinetic potential of the particles with the adsorbed CMC layers and the geometric structure of the layers. (Author abstract) 12 refs.

Efficiency See WATER TREATMENT—Flocculation.

## Electric Field Effects

**081280 ANOMALOUS CHEMOMECHANICAL CHARACTERISTICS OF ELECTRO-ACTIVATED POLYELECTROLYTE GELS.** In a previous article we reported the first model of an electrically activated chemomechanical (mechanochemical) system consisting of mildly crosslinked polyelectrolyte gels. This article reports the anomalous behavior of these and other electro-activated polyelectrolyte gels regarding their rate of contraction under an increasing tensile stress applied to the ends of the gel samples. The rate at which a weight attached to bottom end of the gel was lifted increased with increasing weight. This behavior is believed to be associated with the spontaneous ionization of the polyelectrolyte network due to stretching (reverse-chemomechanical reaction). The article illustrates the contraction behavior of the PMAA gel. 11 refs.

**081281 PREPARATION AND CHARACTERISATION OF PEO-Hg(ClO<sub>4</sub>)<sub>2</sub> COMPLEXES AND SOME THOUGHTS ON ION TRANSPORT IN POLYMER ELECTROLYTES.** A new solid polymer electrolyte, PEO-Hg(ClO<sub>4</sub>)<sub>2</sub>, has been prepared and characterized over a composition range  $100 \leq x \leq 4$ , where  $x$  represents the molar ratio of EO units to salt. Films of this material are amorphous at high salt concentrations and there is no evidence for the formation of a crystalline polymer-salt complex over the entire composition range studied. Electrical measurements indicate that both cations and anions are mobile, with a cation transference number of  $0.25 \pm 0.05$  at  $52^\circ\text{C}$  for an EO/salt molar ratio of 20:1. The overall conductivity of PEO-Hg(ClO<sub>4</sub>)<sub>2</sub> is significantly higher than that of other strictly anhydrous polymer electrolytes containing mobile divalent cations, previously reported. The variation of conductivity with temperature and composition is discussed, and cation mobility in

general is considered in terms of hard and soft character, and in relation to the lability of the coordinated ether oxygens. (Author abstract). 17 Refs.

## Moisture

**081282 MOISTURE SORPTION OF POLYELECTROLYTE COMPLEX BETWEEN POLY(ACRYLIC ACID) AND POLY(4-VINYLPYRIDINE).** Successive differential sorptions have been measured for the system polyelectrolyte complex of poly(acrylic acid)/poly(4-vinylpyridine) + water vapor. The sorption data revealed that the sorption process of water vapor in the complex is controlled not only by diffusion mechanism but also by relaxation mechanism of polymer chains. It has been considered that the complex is composed of a loosely crosslinked, slightly ionized, and relatively homogeneous network structure. The sorption-desorption kinetics have also been investigated for the region of intermediate and high vapor pressures. The interval sorption-desorption curves demonstrated that the complex has the nature of the hysteresis effect in sorptions. (Edited author abstract) 20 refs.

**081283 DETERMINATION OF AVERAGE MOLECULAR WEIGHTS OF A POLYELECTROLYTE BY MENISCUS-DEPLETION SEDIMENTATION EQUILIBRIUM.** This paper describes the application of the method to a high molecular weight sample of the anionic polyelectrolyte sodium poly(styrene sulphonate) (NaPSS), and discusses some particular problems associated with the characterization of polyelectrolytes. Experiments show that number-, weight- and z-average molecular weights of high molecular weight polyelectrolytes may be determined by long-column meniscus-depletion sedimentation equilibrium. Normally it is necessary to utilize a density increment determined on solutions of the polyelectrolyte which have been brought into dialysis equilibrium with a solution of a low molecular weight salt. However, dialysis is not required for the special case of a salt having zero buoyancy factor and having an ion in common with the polyelectrolyte. 29 refs.

## Optical Properties

**081284 STATIC LIGHT SCATTERING STUDIES OF SUSPENSIONS OF CHARGED RODLIKE TOBACCO MOSAIC VIRUS.** In this paper we report on the results of static light scattering. The scattered intensity  $I(q)$  has been measured as a function of scattering vector  $q$  for the five samples. The authors have presented clear evidence of local ordering in dilute suspensions of charged rodlike macromolecules in the light scattering regime. The static structure factor exhibits a pronounced peak even in the neighborhood of  $c$ , where the length of the particles becomes comparable to their mean distance. Since spatial correlations are known to affect considerably the dynamical properties of charged Brownian particles at low ionic strength, our results also help one to understand the dynamic light scattering spectra.

## pH Effects

**081285 EFFECT OF pH ON THE STATE OF THE MICRO-ENVIRONMENT OF POLYELECTROLYTE COMPLEXES FORMED BY SODIUM ALKYL SULPHATES IN AQUEOUS SOLUTIONS.** Spectrophotometric titration of methyl orange has been used to assess the micro-environment of various structural types of complexes with different values of pH in aqueous solutions of polyelectrolyte complexes of the higher alkylsulphates of sodium based on the copolymer formed by N-vinylpyrrolidone and the iodethylate of diethylamino-ethylmethacrylate. It has been shown that the hydrophilic-hydrophobic balance in the microenvironment may be regulated by varying the length of the chain of the sodium alkylsulphate, and by varying the pH and ionic strength of the solution. **081286 ADSORPTION ENHANCED LUBRICATION BY THIN LIQUID FILMS OF SYNTHETIC AND BIOLOGICAL POLYELECTROLYTE SOLUTIONS.** Lubrication properties of three polyelectrolytes such as Na-poly(acrylate), Na-chondroitin sulfate, and Na-hyaluronate were studied by measuring the static friction coefficient  $\mu_s$  of thin liquid films of these aqueous polyelectrolyte solutions between glass surfaces. Adsorption isotherms of the polyelectrolytes onto the glass surface were also measured. Thin liquid films of polyelectrolyte solutions with added NaCl definitely show lubricity. The  $\mu_s$  vs. bulk concentration curves have relevance to the adsorption isotherm and lead to the conclusion that the adsorbed polyelectrolyte layer has the ability to reduce the  $\mu_s$  value of glass-water-glass interface to the extent of 40-60%. (Edited author abstract) 12 refs.

Takahashi, Akira (Mie Univ, Tsu, Jpn); Kozaki, Norio. *Polym J v* 19 n 8 1987 p 945-949.

**081287 EXPERIMENTAL STUDY OF DILUTE POLYELECTROLYTE SOLUTIONS IN STRONG FLOWS.** Flow-induced changes in the conformation of polymer molecules in dilute polyelectrolyte solutions were studied, using birefringence techniques, as a function of molecular weight and added salt concentration in laminar, two-dimensional extensional flows produced in four- and two-roll mills. Overshoots in the flow birefringence during startup of simple-shear flow are presented. Of particular interest is the so-called coil-stretch transition. It is shown that the electrostatic expansion of the polyelectrolyte has a dramatic effect on the onset shear rate for the coil-stretch transition and also on the shape of the flow birefringence versus shear rate curves during the stretching process. A reasonable description of the coil-stretch transition and its dependence on equilibrium configuration is obtained theoretically using a charged dumbbell model with conformation-dependent bead friction. (Edited author abstract) 44 refs.

**081288 SOLUTION PROPERTIES OF POLYELECTROLYTES. I. EXCLUSION CHROMATOGRAPHY OF SODIUM POLYSTYRENE SULPHONATE IN SALT-FREE WATER AS ELUENT.** The effect of concentration of sodium polystyrene sulphonate on the elution volume in exclusion chromatography has been investigated using salt-free water as eluent. A non-linear increase in the elution volume has been observed with increasing injected sample concentration. Concentra-

tion-dependent calibrations have been obtained which approach the universal calibration for uncharged polymers (dextran) as polyelectrolyte concentration increases. The separation mechanisms are interpreted in terms of electrostatic and hydrodynamic interactions. A semi-empirical model is proposed to predict concentration effects of linear polyions in exclusion chromatography and good agreement has been found between experimental and calculated elution volumes. (Author abstract) 51 refs.

Abad, Concepcion (Univ de Valencia, Valencia, Spain); Soria, Vicente; Braco, Lorenzo; Garcia, Rosa; Campos, Agustin. *Br Polym J* v 19 n 6 1987 p 489-500.

**081289 SOLUTION PROPERTIES OF POLYELECTROLYTES. II. COMPARISON OF THE EFFECTS OF BOTH POLYION AND ELUENT SALT CONCENTRATIONS ON THE CALIBRATIONS IN AQUEOUS EXCLUSION CHROMATOGRAPHY.** The elution behaviour of charged water-soluble polymers (sodium polystyrene sulphonate) in both salt-free and NaCl-containing aqueous mobile phases has been investigated by size-exclusion chromatography. A comparative analysis has been established between the results as a function of polyion and salt concentrations, which demonstrates that the chromatographic behaviour is similar in both cases. The variation of the slopes of the different concentration-dependent calibration curves is discussed in terms of polyelectrolyte conformational changes. (Edited author abstract) 23 refs.

Abad, Concepcion (Univ de Valencia, Valencia, Spain); Braco, Lorenzo; Soria, Vicente; Garcia, Rosa; Campos, Agustin. *Br Polym J* v 19 n 6 1987 p 501-508.

**081290 RHEOLOGY OF XANTHAN GUM: SALT, TEMPERATURE, AND STRAIN EFFECTS IN OSCILLATORY AND STEADY SHEAR EXPERIMENTS.** Dynamic oscillatory shear testing has been used to study the rheology of xanthan gum in the moderate concentration regime ( $500 < c < 5000$  ppm). The dynamic moduli of two industrial grade xanthan gums (a dried powder and a fermentation broth) have been compared in deionized, distilled water (low salt) and in 0.5% NaCl solutions (high salt). Detailed studies of the effects of salt, temperature, and high shear on 5000 ppm xanthan gum solutions in dynamic, steady, and transient shear have been conducted. A master curve of the dynamic properties covering six decades of frequency has been obtained for xanthan gum in highly saline solutions. (Edited author abstract) 32 refs.

Rocheffort, Willie E. (Univ of California, La Jolla, CA, USA); Middleman, Stanley. *J Rheol* v 31 n 4 May 1987 p 337-369.

**081291 VISCOSITIES OF COPOLYPHOSPHATES IN SALT-FREE AQUEOUS SOLUTIONS AND THETA SOLVENTS.** The results of viscosity measurements on several samples of lithium-potassium copolyposphates (Li:K ratio ranging from 9:1 to 5:5) in salt-free aqueous solutions and in theta solvents are reported. Molecular weights determined by end-group titration ranged from 4000-10,000. In aqueous solutions the Fuoss equation parameter A was found to be nearly proportional to the square of molecular weights, indicating rod-like structures of the poly-ions at infinite dilution. The concentrations of NaBr solutions acting as theta solvents at 35°C were determined for all cases and the viscosity data in  $\theta$ -solvents were utilized in calculating unperturbed dimensions which were found to lie in the range  $4.7 \times 10^{-7}$  cm to  $7.4 \times 10^{-7}$  cm. (Author abstract) 19 refs.

Bhargava, H.N. (Gorakhpur Univ, Gorakhpur, India); Srivastava, Rita Rani; Singh, Manju. *Polym J* v 19 n 11 1987 p 1285-1292.

**081292 COUNTERION ACCUMULATION IN ROD-LIKE POLYELECTROLYTE SOLUTIONS WITH ADDED SALT AND MANNING'S CONDENSATION THEORY.** The Poisson-Boltzmann equation in the cylindrical cell model is solved numerically for charged polyelectrolyte solutions containing mono- or

divalent counterions and monovalent coions. The results, which describe the ion distribution around the polyion, are compared with those derived from the Poisson-Boltzmann equations for salt-free solutions in the limit of infinite dilution and with the Manning counterion condensation theory. The general conclusion drawn not only supports further evidence that the Manning condensation theory can be deduced from the Poisson-Boltzmann equation but also suggests that counterion binding changes progressively from a free to condensed phase, as the polyion charge density parameter increases. (Edited author abstract) 19 refs.

**081293 COUNTERION SELECTIVITY IN CATIONIC POLYELECTROLYTES.** Chloride ion activity coefficients in aqueous solutions of several cationic copolymers have been determined using ion-selective electrodes in both the absence and the presence of simple univalent and divalent salts. Without added salt, the activity coefficient depends on the polymer concentration. It increases with increasing concentration of the added salt. The extent of interaction between counterions and polyions at a given polymer concentration, as estimated from chloride anion activity, is greater for bivalent than for univalent anions. Experimental data are in good agreement with theory. (Edited author abstract) 46 refs.

**081294 ELECTROLYTIC CONDUCTIVITY OF POLY(1,3-PROPYLENE PHOSPHATE) SOLUTIONS CONTAINING MONO- AND DIVALENT-COUNTERIONS.** The results of conductivity measurements for aqueous solutions of poly(1,3-propylene phosphate) (PPP), which can be considered as a synthetic analogue of naturally occurring teichoic acids, are reported. Experiments were carried out with oligomeric fractions of a polymer in acidic, sodium, potassium, magnesium and calcium forms. The concentration and molecular weight dependence of the equivalent conductivity of PPP was analysed and the limiting equivalent conductivity determined. From the conductivity data, the polyion-counterion interaction parameter F and the equivalent conductivity of a polyion  $\lambda_p$  were calculated. It was shown that both F and  $\lambda_p$  depend on polyelectrolyte solution concentration and molecular weight of PPP. Conclusions concerning mono- and divalent metal ions binding to PPP are drawn. (Author abstract) 32 refs.

**081295 INVESTIGATION OF ION BINDING PROPERTIES OF SYNTHETIC POLYELECTROLYTES USING A TERBIUM (III) PROBE: ELUCIDATION OF THE NUMBER OF COORDINATED WATER MOLECULES ON METAL POLYELECTROLYTE COMPLEXES.** Determination of the hydration state of a metal ion bound in a polymer matrix can be used to deduce its coordinative environment. Consequently, we have studied the fluorescence properties of Tb(III) bound to polycarboxylates, as well as to simpler monomeric carboxylate ligands. The results of these investigations are the subject of this work. Upon addition of poly(sodium acrylate) to an aqueous solution of Tb(III), it was found that the Tb(III) fluorescence intensity was greatly increased. Repeat of the same experiment in  $D_2O$  led to an approximate order of magnitude increase in emission intensity. 21 refs.

**081296 VISCOSITY OF POLYELECTROLYTE SOLUTIONS-THE GENERALIZED FUOSS LAW.** Early studies of the viscosity of semidilute and moderately dilute 'salt-free' polyelectrolyte solutions have led to the

empirical relation between the reduced viscosity and the monomeric concentration known as the Fuoss law. The anomalously large values of the intrinsic viscosity obtained by this method are taken as an indication that polyions become fully stretched in the dilute limit. In fact, the intrinsic viscosity is of the same order of magnitude as that of neutral polymers of similar molecular weight, indicating that, even in this limit, the macroion conformation bears a closer resemblance to an expanded coil than to a rigid rod. Using a modified version of the theory originally developed by Hess and Klein for suspensions of highly charged, spherical particles, the authors obtained the new expression for the viscosity, the generalized Fuoss formula for analyzing the results of experiments on the viscosity of the dilute and semidilute polyelectrolytes. 21 Refs.

## Structure

**081298 PERMEABILITY CONTROL OF POLYELECTROLYTE COMPLEX MEMBRANE INCLUDING CHITOSAN DERIVATIVE AS A COMPONENT.** The properties of polyelectrolyte complexes (PEC) and PEC membranes were investigated in the systems of glycol chitosan (GC)-poly(vinyl sulfate) (PVSK) and methyl glycol chitosan (MGC)-(carboxymethyl)dextran (CMD). The degree of dissociation and the conformation of GC and CMD depend upon pH, because GC and CMD are weak polybase and weak polyacid, respectively. On the basis of this knowledge, a research into the pH dependence of dissociation and viscosity of GC and CMD was carried out. PEC including chitosan derivative as a constituent was synthesized at the adequate pH, pH 3.0 in the GC-PVSK system and pH 7.0 in the MGC-CMD system. PEC membranes were prepared, and the permeability of KCl, urea, and sucrose through the GC-PVSK membrane was determined under various pH. It was revealed that the permeability of KCl, urea, and sucrose varies with the solution pH. This work is pertinent to drug delivery systems. (Edited author abstract). 19 refs.

## Synthesis

**081300 CHEMICAL RESISTANCE OF MATERIALS IN SYNTHESIS OF POLYELECTROLYTE PKB-1.** A process has been developed for the synthesis of a highly efficient cationic polyelectrolyte (polydimethyldiallylammonium chloride), product designation PKB-1. In the synthesis process, the starting materials and also the products are corrosive. With the aim of determining the resistance of materials and developing a material design specification for the process of manufacturing the polyelectrolytes, the authors tested the corrosion resistance of a number of materials. 6 refs.

Danilov, I.N. (Bashkirian Scientific-Research Inst for Petroleum Processing, USSR); Ishmaeva, A.M.; Kuznetsov, V.A. *Chem Technol Fuels Oils* v 23 n 3-4 Mar-Apr 1987 p 123-125.

**081301 POLYELECTROLYTES CONTAINING IMIDAZOLYL GROUPS PREPARED FROM POLYSTYRENE FOR HYDROLYSIS OF PHENYL ESTERS.** Polyelectrolytes containing imidazolyl groups, which are soluble in water, have been prepared by treating chloromethylated polystyrene first with triethylamine to convert a part of chloromethyl groups to quaternary ammonium groups and then with histamine or histidine. Hydrolyses of several phenyl esters in the presence of the polyelectrolytes were much faster than those in the presence of small molecules containing an imidazolyl group such as histamine, histidine, or imidazole. The hydrolyses catalyzed by the polyelectrolytes conformed to Michaelis-Menten kinetics, except for the case of 3-acetoxy-N,N,N-trimethylanilinium iodide. The higher rate in the presence of the polyelectrolytes was due to the lowering of free energy by the formation of associated complexes between the polyelectrolytes and the substrate. The driving force of the complex formation was substantially hydrophobic interaction; however, hydrogen bonding and electrostatic attraction are suggested in some cases. (Edited author abstract) 34 refs. In Japanese.

Kawabe, Hiroshi (Chiba Inst of Technology, Narashino, Jpn). *Kobunshi Ronbunshu* v 45 n 2 1988 p 177-184.

**081302 NEW CLASS OF CATION CONDUCTORS: POLYPHOSPHAZENE SULFONATES.** The authors report the synthesis and conductivity of a new class of polyelectrolytes having phosphazene backbone and with sulfonate and oligoether side chains. As a model system for the analogous reaction with linear poly(dichlorophosphazene),  $[\text{NPCl}_2]_n$ , the authors investigated the equimolar reaction of hexachlorocyclotriphosphazene,  $\text{N}_3\text{P}_3\text{Cl}_6$ , with the disodium salt of 2-hydroxyethanesulfonic acid,  $\text{NaOC}_2\text{H}_4\text{SO}_3\text{Na}$ , in THF in the presence of 15-crown-5. The alkoxysulfonate acts as a difunctional reagent toward  $\text{N}_3\text{P}_3\text{Cl}_6$ .  $^{31}\text{P}$  NMR spectra gave no indication of the presence of spirocyclic or ansa products. Also, intensities in the  $^{31}\text{P}$  NMR gave no evidence for intermolecular condensation products. The ratio of the sulfonate group to the ether side groups is established by the ratio of the integral intensities of  $\text{OCH}_2$  protons with  $\text{CH}_2\text{S}$  protons from  $^1\text{H}$  NMR spectra. In addition, qualitative tests using  $\text{Ag}^+$  demonstrated the lack of appreciable chloride in the product. The general synthetic procedure employed should permit the attachment of a wide variety of pendant charged groups to the phosphazene backbone. 16 refs.

**081303 WPLYW STOPNIA POLIMERYZACJI NA WLASCIWOSCI FOTOCHIMICZNE POLIESTRU NA PODSTAWIE BEZWODNIKA KWASU 3-AZIDO-O-FTALOWEGO I POLI(ALKOHOLU WINYLOWEGO).** (Effect of the Degree of Polymerization on the Photochemical Properties of a Polyester on the Basis of 3-Azido-Orthophthalic Anhydride and Poly(Vinyl Alcohol).) In polyesterification of PVA fractions of different molecular mass with 3-azido-orthophthalic anhydride, samples of poly(vinyl ortho-azidophthalate) of different degrees of polymerization ( $n$ ) have been prepared. It has been found that an increase of the degree of polymerization of this photopolymer which absorbs radiation in the range 220-350 nm is accompanied by an increase in the total sensitivity, whereas after exceeding a defined value of  $n$  its sensitivity becomes independent of the degree of polymerization. An addition of 2,6-dichloro-4-nitroaniline as a sensitizer shifts the spectral sensitivity of this polymer in the direction of longer waves and increases its total sensitivity. (Edited author abstract). 7 Refs. In Polish.

**081304 CHAIN EXTENDERS FOR POLYESTERS. VI. PROPERTIES OF THE POLYESTERS CHAIN-EXTENDED BY 2,2'-BIS(4H-3,1-BENZOXAZIN-4-ONE).** Some properties of polymers derived by treating poly(ethylene terephthalate) (PET) with such hydroxyl-addition-type chain extenders as 2,2'-bis(4H-3,1-benzoxazin-4-one) (BNZ) were investigated. Compared with ordinary PET, the chain-extended PET has a slightly lower melting point and nearly equal molecular size distribution, which indicate that BNZ reacts to form linear chain-extended polymers without branching. Oxalyl bis(anthranelate) unit copolymerized in the polyester chain showed little influence on thermal and hydrolytic stabilities. In addition, benzoxazinone groups remaining unreacted can act as a heat stabilizer to prevent the decrease in the molecular weight by the chain-extending reaction in the solid phase. But they showed adverse effect on the hydrolytic stability by promoting hydrolysis of the polymer as much as the carboxyl groups. (Author abstract) 4 refs.

**Applications** See Also CONCRETE CONSTRUCTION—Protective Coatings; ELECTRIC WINDINGS—Plastics Applications; ELECTRIC WINDINGS, MACHINE; OPTICAL FIBERS—Coatings; PROTECTIVE COATINGS—Powder.

**081305 UNSATURATED POLYESTER RESINS AND VINYL ESTER RESINS.** Discovered over 50 years ago and on the market for nearly 40 years, unsaturated polyester resins have long ranked among the —mature products—. Nevertheless, consumption in the Federal Republic of Germany rose from 58 000 t in 1984 to 63 000 t in 1986. New or increased applications in the transport sector and environmental protection more than compensate for the further decline in conventional applications such as corrugated sheeting and in boatbuilding. The vinyl ester resins (VE) used in the polyesters are condensation resins, which like UP resins cure by free-radical copolymerization with styrene. Their proper-

ties lie between the UP and epoxy resins. In German standardization groups it has been proposed that they be known as phenacrylate resins. The VE resins open up new fields of application for GRP, e.g. in the form of clean-gas pipes and flue gas scrubbers used in coal-fired power stations. In line with the increased environmental awareness, sewage treatment tanks are being increasingly fitted with large-span GRP covers. 30 refs.

## Biocompatibility

**081307 STUDY OF THERMAL AND GROSS MORPHOLOGIC PROPERTIES OF POLYGLYCOLIC ACID UPON ANNEALING AND DEGRADATION TREATMENTS.** The objective of this study is to alter fiber morphology of a linear aliphatic polyester, polyglycolic acid, by annealing treatment and to examine the changes of its degradation properties. The annealing was done at 150°C, 170°C, and 190°C, and specimens were annealed in four different strained conditions, freely hung, 0, 1, and 10 percent. After annealing, specimens were subject to in vitro hydrolytic degradation by immersion in phosphate-buffer solution of pH 7.4 at 37°C for up to 28 days. The thermal properties and gross morphology of the specimens were obtained. It was found that annealing treatments resulted in initial higher levels of crystallinity, which, in turn, influenced the hydrolytic degradation of the fiber. Among all the annealing conditions, the freely hung specimens annealed at 190°C exhibited the most pronounced annealing effect on hydrolytic degradation, consistent with observed gross morphologic changes. The change to a less oriented conformation was thought to be the cause. (Edited author abstract). 20 Refs.

Chu, C.C. (Cornell Univ, Ithaca, NY, USA); Browning, A. *J Biomed Mater Res* v 22 n 8 Aug 1988 p 699-712.

## Biodegradation

**081308 SYNTHESIS AND BIODEGRADATION OF COPOLYESTERS DERIVED FROM GLUTAMIC ACID.** Copolymers of glutamic acid hydrochloride and 1,2-ethane diol, 1, 3-butane diol, 1,4-butane diol, 1,6-hexane diol and glycerol have been synthesized and characterized by number average molecular weights, I.R. spectra and elemental analysis. Microbial degradation of the co-polyesters has been studied using the fungus *aspergillus niger* and the bacterium *E.coli*. All the polymer samples are degraded by these microorganisms. The less polar copolymers are more readily degraded by the fungus while the bacterium more efficiently degrades the polymers having a higher proportion of  $\alpha\text{-NH}_2$  group. The facile attachment of a suitable drug through the free amine groups of the copolymers has been illustrated to indicate their possible use as carrier polymers for drugs. (Edited author abstract) 11 refs.

**Blending** See Also SYNTHETIC FIBERS—Processing; TEXTILE FIBERS—Synthetics.

**081309 COMPATIBILITY AND MESOPHASE SEPARATION IN BLENDS OF  $\alpha$ -HELICAL POLY-**

**GLUTAMATES.** Blends composed of the  $\alpha$ -helical polymers, poly-L-glutamates  $[(\text{NHC}^{\alpha}\text{HRC}^{\alpha}\text{O})_n]$ ,  $R = \text{CH}_2\text{CH}_2\text{COO}-(\text{CH}_2)_m\text{C}_6\text{H}_5]$  (Lm) and the corresponding D enantiomers (Dm), have been studied by x-ray diffraction and viscoelastic measurements. Binary blends of L2, D2, L3, and D3 are compatible and form isomorphous mixed crystals at all compositions, whereas other pairs, with the exception of L1/D1, are incompatible. The demixing process is described for a ternary system consisting of L1, D3, and a diluent chloroform at 40°C. The phase diagram comprises four regions, I, IA, A, and AA, with increasing polymer concentration; I: isotropic, A: anisotropic, IA: I-A biphasic, and AA: A-A biphasic. The IA biphasic gap is greater in the ternary system than in the binary ones. The high-molecular-weight component (D3) is partitioned into the A phase in the IA region. The AA separation originates from incompatibility of the polymers. The phase behavior is discussed on the basis of the Abe-Flory theory by incorporating the polymer-polymer interaction parameter. **081310 SIMULTANEOUS DETERMINATION OF PHTHALIC ACIDS AND POLYOLS IN LINEAR SILICONE POLYESTERS.** A procedure is described which simplifies previously reported methods applicable to hydrolysis-resistant polyesters. Elimination of the extraction steps has been achieved in an attempt to provide a simultaneous estimation of polyol acetates and dimethyl carboxylates, to remove errors introduced by the extraction steps, and accordingly to improve the quantitative nature of the analysis. The degradation was conducted using an acetic anhydride-acetic acid reagent. Acetic acid present and formed during the reaction was removed by distillation and the dicarboxylic acids esterified with boron trifluoride-methanol reagent. Complete acetylation of the polyols was achieved by reaction in the presence of 1-methylimidazole. The organic pendant groups of the siloxane components are split off as the corresponding hydrocarbons by both acid or alkaline reaction. The methane and benzene thus formed are estimated by gas solid chromatography using a head space technique. (Author abstract) 23 refs.

**081311 FOTONICJOWANE SIECIOWANIE NIENASYCONYCH ZYWIC POLIESTROYCH TYPU POLIMAL WOBEC ETTEROW BENZOINY JAKO FOTONICJATOROW.** [Photoinitiated Crosslinking of Polimal Type Unsaturated Polyester Resins in the Presence of Benzoic Ethers]. The Polish-made unsaturated polyesters of the Polimal type have been photopolymerized in UV-range with the use of lower alkyl ethers of benzoic as initiators. For the system of Polimal 103 - benzoic isobutyl ether the dependence of the surface hardness, impact strength and softening temperature of the cured samples on photoinitiator concentration has been determined. Using an original measuring system the thermal effects of the photoinitiated polymerization in the presence of various amounts of initiator have been measured. The course of the photo- and thermoinitiated by benzoyl peroxide crosslinking of Polimal resins as well as the properties of crosslinked resins from both processes have been compared. **081313 POSTCROSSLINKING OF LINEAR POLYESTERS. I. MELT-BLEND-TYPE UV-INDUCED CROSSLINKING AGENTS.** Postcrosslinking of such linear polyesters as poly(ethylene terephthalate) (PET) and poly(butylene terephthalate) (PBT) are known to be attractive means to improve their thermal resistance without sacrificing their melt processibilities. Effective melt-blend-type ultraviolet-induced crosslinking agents were investigated among allyl compounds. Such polyallyl compounds as triallyl cyanurate and triallyl isocyanurate were found to be practically promising agents from the viewpoints of crosslinkability and stability in the polyester melt. The crosslinkability of the allyl compounds increased with increasing the number of the allyl groups in the molecule and electron-withdrawing property of the neighboring group to which the allyl group was attached. The crosslinked PET and PBT showed good mechanical properties even above the melting points of the ordinary PET and PBT. (Edited author abstract) 13 refs.

**081314 CRYSTALLIZATION AND MORPHOLOGY OF POLY( $\beta$ -HYDROXYBUTYRATE) AND ITS COPOLYMER.** The morphology and structure of the bacterial plastics of poly( $\beta$ -hydroxybutyrate- $\beta$ -hydroxyvalerate) P(HB-HV) were studied as well as the reference homopolymer, poly( $\beta$ -hydroxybutyrate) (PHB). Because of bacterial origins they are exceptionally pure. The solution-grown single crystals of PHB and P(HB-HV) showed linear increase in melting points and hyperbolic increase in long spacings as the crystallization temperature increased. The HV component in the polymer chain was inclined to be excluded outwards as much as possible from the crystal of HB component during the crystallization. A small part of the HV component included in the HB component crystal acts as a defect, by which small expansion of the a-parameter of the unit cell is mainly caused with increasing HV content. The severe effect of the HV component was observed on crystallization characteristics and morphological changes. (Edited author abstract) 32 refs.

**081315 EFFECT OF PRESSURE ON THE CURING BEHAVIOR OF UNSATURATED POLYESTER RESINS.** The effect of pressure on the curing behavior of unsaturated polyester resin was investigated, both experimentally and theoretically. The resin used was a general-purpose unsaturated polyester resin and the initiator used was t-butyl perbenzoate. A series of isothermal runs with differential scanning calorimetry (DSC) were made at various levels of cure pressure. It was found that the rate of cure was retarded under pressure, and that the ultimate degree of cure went through a maximum at a certain

pressure at the cure pressure was increased from atmospheric pressure to 6.21 MPa (900 psi). It was interpreted that pressure has two competing effects on the curing behavior of unsaturated polyester resin; one is a free volume effect that hinders the curing reaction and the other is a thermodynamic effect that favors it. (Edited author abstract) 15 refs.

**081317 ESR STUDY OF THE CURING REACTION OF UNSATURATED POLYESTER WITH VINYL MONOMERS AND THE THERMAL BEHAVIOR OF THE CURED POLYMERS.** The curing reaction of an unsaturated polyester (BAPM), prepared by polycondensation of Bisphenol A-di-(2-hydroxypropyl)ether and maleic anhydride, with vinyl monomers was investigated by IR and ESR. Thermal properties of the resulting polymer were studied by DSC and TMA. For the curing reaction of BAPM with styrene initiated with the cobalt naphthalate/1-hydroxycyclohexyl hydroperoxide system, the copolymerization process could be satisfactorily analyzed by the Mayo-Lewis integral equation for the usual homogeneous copolymerization. The reaction mixtures contained long-lived polymer radicals, the ESR spectra of which gave important information on the curing reaction. (Edited author abstract) 21 refs.

**081320 THERMODYNAMIC ASPECTS OF DEGRADATION WITH PARTICULAR REFERENCE TO UNSATURATED POLYESTER RESINS.** Like the concept of ceiling temperature, which allows the prediction of when a depolymerization reaction can occur from the thermodynamic point of view, it is pointed out that degradation reactions other than depolymerization can be treated in an analogous manner. Calculations on the basis of increments are particularly useful because the increments of parts of the molecule which are not involved in the reaction process do not occur explicitly in the calculation. Thus, for certain types of reaction, typical thermodynamic data can be obtained. Thermodynamic data of some typical reactions which are of importance in the field of the thermal degradation of unsaturated polyester resins are calculated. The results are compared with experimental results obtained from previously published research in the field of polyesters. (Edited author abstract). 12 Refs.

## Electric Properties

**081323 ELECTRICAL PROPERTIES OF POLYESTER POLYMER-QUINOLINE SALT OF TETRACYANOQUINODIMETHANE COMPOSITES.** The purpose of this note is to present preliminary measurements of the electrical properties of polyester polymer-quinoline salt of tetracyanoquinodimethane composites which are also characteristic of a low critical

concentration of the conducting component ( $< 1$  wt%). The polyester polymer compositions have been obtained by polymerization of styrene solution of unsaturated polyester (Polimal 109). The electrical conductivity of polyester polymer Polimal 109 is thermally activated and of ionic character and amounts of  $10^{-17} \Delta^{-1} \text{ cm}^{-1}$  at room temperature. By adding  $> 1$  wt% needle-like crystals an abrupt increase of the electrical conductivity by ten orders of magnitude has been observed. Classic bond or site percolation models cannot account for threshold concentrations as low as 1% nor for a critical exponent as large as 7.6 which were observed in this work. The comparison of two  $c = 10^{-2}$  data points demonstrates the importance of the shape factors for the formation of a conducting network and percolative charge transport. 7 refs.

## Environmental Impact

**081324 TIGHTER RULES ON ALLOWABLE EMISSIONS YIELD SAFER MATERIALS AND EQUIPMENT.** On July 1 four southern California counties will enact a regulation limiting the amount of volatile organic compounds that reinforced polyester fabricators can release into the air. The target of the measure (Rule 1162) is styrene monomer emissions that occur during fabrication, chiefly sprayup and layup. Efforts to reduce styrene emissions and improve properties may lead some fabricators to consider hybrid polyesters. Spray equipment is a factor in controlling volatile organic compounds - thus codes/regulations have led equipment suppliers to lower sprayup pressures and redesign guns.

## Extrusion

**081325 INDUCTION OF PREFERRED ORIENTATION IN A LIQUID CRYSTAL CO-POLYESTER BY EXTRUSION AND DRAWING.** It is shown that liquid crystal polyester can be extruded and drawn from the melt into fine fibers which possess stiffnesses up to 68 GPa. Thicker fibers with smaller draw ratios have correspondingly lower stiffnesses, which are correlated with molecular alignments characterized by flat plate X-ray diffraction. Fibers with a range of diameters were heat-treated over a range of temperatures to determine the effect of annealing on preferred orientation and stiffness. Heat-treatment of as-spun fibers produced maxima in axial stiffness at 170°C, corresponding to an increase in preferred orientation, and 270°C, corresponding to the development of quasi-crystalline order which is analyzed. Scanning electron microscopy showed the existence of needle-like domains of approximately circular cross section up to 0.8  $\mu\text{m}$  in diameter. These were aligned in the direction of drawing in contrast to being haphazardly arranged in a hot rolled specimen displaying no preferred orientation. (Author abstract) 14 refs.

Jenkins, J.C. (Univ Coll of Swansea, Swansea, Wales); Jenkins, G.M. *J Mater Sci* v 22 n 10 Oct 1987 p 3784-3792.

**081326 EXTRUSION, FIBER FORMATION, AND CHARACTERIZATION OF THERMOTROPIC COPOLYESTERS.** The flow behavior and the effect of the spinning conditions on the fiber properties and structure of poly(ethylene terephthalate) modified with 60 mol% p-hydroxybenzoic acid (PET/60PHB) were investigated. PET and its copolymers with 28 and 80 mol% PHB were used as control samples. The melt of PET/60PHB at temperatures above 265°C exhibited extremely low viscosity and low flow activation energy. High birefringence, indicating the presence of a mesophase, was observed between 265 and 300°C on a hot-stage polarizing light microscope. The maximum tensile strength and initial modulus, 438 MPa and 37 GPa, respectively, were

obtained at 275°C for a 0.69 IV polymer. The fiber strength and modulus were significantly lowered when extrusion was conducted at temperatures below 265°C. The fiber properties could also be improved when a high extrusion rate and/or a high draw down ratio was used. Scanning electron microscopy revealed that the fibers spun at temperatures above 265°C had a well-developed, highly oriented fibrillar structure. The fibers spun at lower temperatures, however, were poorly oriented and nonfibrillar in character. The high orientation and superior mechanical performance achieved at high temperatures were attributed to the presence of the nematic mesophase in the polymer melt. (Author abstract) 31 refs.

Cuculo, John A. (North Carolina State Univ, Raleigh, NC, USA); Chen, Gao-Yuan. *J Polym Sci Part B* v 26 n 1 Jan 1988 p 179-200.

## Fiber Reinforcement

**081327 DIFFUSION OF HYDROCHLORIC ACID IN POLYESTER THERMOSETTING RESINS.** The possibility of diffusion of corrosive media in polyester resins is considered as a contributor to the process of stress corrosion cracking in glass reinforced polyester composites. It is shown that neither the saturation levels reached nor the rate of diffusion achieved for hydrochloric acid is sufficient for this mechanism to be considered a significant contributor to the process of low stress induced corrosion. It is believed that the corrosive medium will attack the fibers by a process of percolation through stress induced microcracks. (Author abstract) 13 refs.

Caddock, B.D. (Univ of Liverpool, Liverpool, Engl); Evans, K.E.; Hull, D. *J Mater Sci* v 22 n 9 Sep 1987 p 3368-3372.

## Filaments

**081328 MELT SPINNING OF THERMOTROPIC LIQUID-CRYSTAL POLYESTERS TO FORM ULTRAHIGH-MODULUS FILAMENTS.** The properties and structure of ultrahigh-modulus filaments were investigated for wholly aromatic copolymers (WACPs) containing 60 and 70 mol percent p-oxybenzoate, based on p-hydroxybenzoic acid, p, p'-biphenol, terephthalic acid, and isophthalic acid and for poly(ethylene terephthalate co-p-oxybenzoate) containing 60 mol% p-oxybenzoate. As-spun filaments with varying degrees of molecular orientation were spun from melts by taking the spin-extension ratio as a variable at given temperatures. The as-spun filaments were further subjected to thermal annealing. Changes in the structural ordering with the extension ratio were monitored by wide-angle x-ray scattering, scanning electron microscopy, viscoelastic properties, and measurements of the thermal expansion coefficient. The increase in modulus is correlated well with the crystallite orientation at a relatively low extension ratio. (Edited author abstract) 19 Refs.

Itoyama, Kuniyoshi (Research Assoc for Basic Polymer Technology, Tokyo, Jpn). *J Polym Sci Part B* v 26 n 9 Aug 20 1988 p 1845-1863.

## Fillers

**081329 MOISTURE ABSORPTION IN UNFILLED AND GLASS-FILLED, CROSS-LINKED POLYESTER.** The moisture uptake characteristics of unfilled and filled polyester resin at 60°C are reported. The objective was to determine the influence of filler on the moisture uptake properties of unfilled polymer. Diffusivity in the filled polyester is lower than in the plain resin. However, the filled resin absorbs significantly more water than unfilled polyester. Tensile load was found to have no effect on the water uptake in plain polyester. However, moisture absorption was affected by tensile load in 20% (by volume) bead-filled polyester and in SMC-R65. In bead-filled polyester, the diffusion coefficient was accurately predicted when microstructural effects were accounted for. (Edited author abstract) 26 refs.

Janas, V.F. (Univ of Delaware, Newark, DE, USA); McCullough, R.L. *Compos Sci Technol* v 29 n 4 1987 p

293-315.

**081330 PARTICULATE FILLED POLYESTER COMPOSITES.** In this note we examine the effect of two different fillers, one hard and the other a soft filler, on some physical properties of an unsaturated polyester resin. An unsaturated polyester resin prepared from maleic anhydride, ethylene glycol and isophthalic acid in styrene monomer was employed. Sand particles with dimensions of approximately 100  $\mu\text{m}$  were used. Cryogenically ground rubber (CGR) from old tires of approximately 250  $\mu\text{m}$  was also employed. This study showed that the final properties of particulate composites are strongly affected by the intrinsic nature of the filler. The acoustic emission, an indication of the microcracking activity in the composite during deformation, showed that the hard filler (sand) gave more acoustic emission than a soft filler (CGR). 2 refs.

## Flame Resistance

**081332 REDUCTION IN THE COMBUSTIBILITY OF UNSATURATED POLYESTER RESINS.** Halogen- or phosphorus containing organic compounds or synergistic metal oxides are the main means of imparting flame retardancy to unsaturated polyester resins. They are intended not only to inhibit combustion but also to reduce the formation of toxic gases and smoke development. Commercial flame retardants for UP resins and their model of action are reviewed. (Author abstract) 44 refs. In German and English.

**081333 FLAMEPROOF POLYESTERS PREPARED BY DIRECT POLYCONDENSATION OF AROMATIC DICARBOXYLIC ACIDS AND BROMINATED BISPHENOLS WITH TOSYL CHLORIDE AND N,N'-DIMETHYLFORMAMIDE IN PYRIDINE.** Brominated aromatic polyesters were successfully prepared by reacting isophthalic acid and terephthalic acid with p-toluenesulfonyl chloride in pyridine in the presence of N,N'-dimethylformamide, followed by treating with a pyridine solution of tetrabromobisphenols. The tetrabromobisphenols were synthesized by a facile bromination of their corresponding bisphenols in aqueous acetic acid solution under mild conditions. The polycondensation was significantly affected by the reactivity of bisphenols and the solubility of the resulting polymers in the reaction media. Tetrabromobisphenols with positive linking groups between the aromatic rings and better solubility of the resulting polymers give a more favorable result. The products were nonflammable having limiting oxygen index 59-62 (ASTM D2863-77) without much sacrifice in thermal stability. (Author abstract). 13 Refs.

## Heat Treatment

**081335 THERMOTROPIC POLYESTER CARBONATES. II. POLYESTER CARBONATES AS HIGH PERFORMANCE FIBERS.** The fiber spinning and heat treatment of spun fibers from thermotropic polyester carbonates are described. Thermotropic polyester carbonates derived from t-butylhydroquinone, methylhydroquinone, diphenyl terephthalate, and diphenyl carbonate in the molar ratios of 50:50:55:45; 50:50:57.5:42.5; can be spun successfully, and after proper heat treatment, yield fibers with tenacity as high as 20 g/denier. Normally the best spinning temperature is 10-20°C above melting. (Author abstract). 4 Refs.

Lai, Y.C. (Allied-Signal Inc, Morristown, NJ, USA); Debona, B.T.; Prevorsek, D.C. *J Appl Polym Sci* v 36 n 4 Aug 5 1988 p 805-817.

## Hydrolysis See AROMATIC POLYMERS—Hydrolysis; TEXTILE FIBERS—Synthetics.

## Mechanical Properties See Also VINYL RESINS.

**081336 AROMATIC POLYESTERS AND POLYESTER CARBONATES.** With aromatic polyesters and polyester carbonates a new family of plastic materials has been available for a few years which is closely related to polycarbonates and can be regarded as a further development of the latter. Aromatic polyesters are mainly prepared by polycondensation of Bisphenol A with terephthalic or isophthalic acid derivatives. For the manufacture of polyester carbonates carbonic acid derivatives are in addition used. Owing to their property profile polyarylates offer application possibilities in many areas. The transparency and weak natural colour with a high deflection temperature under load allow these plastics to be used in lighting technique for highly stressed light coverings, lenses and scattering discs. In the technical development emphasis is on the use of polyarylates for polyblends with special property combinations and the adaption of the products to meet the demands of the processor. 4 refs.

Rathmann, D. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 57-59.

**081337 STUDIES ON THERMOTROPIC AROMATIC COPOLYESTERS: P-HYDROXYBENZOIC ACID 2, 3, 5-TRIMETHYLBENZOIC ACID, 2, 6-NAPHTHALENE DICARBOXYLIC ACID SYSTEM.** A series of aromatic copolymers based on the p-hydroxybenzoic acid (HBA), 2,3,5-trimethylhydroquinone (TMHQ), and 2,6-naphthalene dicarboxylic (NDA) system was synthesized. The effect of composition of aromatic copolymers on their liquid crystalline behavior, rheological property, thermal stability and crystal structure was studied. It was found that they exhibited a threaded schlieren texture in a quiescent melt state and formed banded structure under shearing conditions, manifesting that a nematic mesophase existed. The thermal stability of the copolymers containing 15-20mol percent

TMHQ and NDA was considerably improved. As the ratios of PET/HBA increased both the melting point and degradation temperature of the copolymers having the same amounts of TMHQ and NDA decreased. The extrudates from the capillary die for them exhibited highly oriented morphologies. (Author abstract). 13 Refs.

Liang, Borun; Ke, Jiaqin; Huang, He; Yu, Hu. *J China Text Univ Engl Ed* v 5 n 1 Mar 1988 p 79-86.

**081338 POLYESTER: TECHNICAL AND COMMERCIAL VIEW.** Polyester is the world's second largest fiber in production tonnage and is in a growth position owing to its recent (1982-86) high rate of increase (15 percent p/a) in developing and centrally-planned countries. Moreover, about 70 percent of immediately-planned new fiber capacity is for polyester. The reasons for this success lie in a combination of technical and commercial merits of the fiber-making system, and of the wide applicability of polyester fibers to textile products. Comparisons of the major uses of the principal man-made fibers (polyester, polyamide, acrylic, viscose etc.) show that polyester has the widest scope of usage both in fiber and yarn types and in end-products.

Ford, John (British Textile Technology Group, Manchester, Engl). *Text Mon* Oct 1988 p 27, 29-32.

## Melting

**081339 MULTIPLE ENDOTHERMIC MELTING BEHAVIOR IN POLY(TETRAMETHYLENE TEREPHTHALATE)-CONTAINING POLYESTERS AND BLOCK COPOLYETHER-ESTERS.** The multiple endothermic behavior of poly(tetramethylene terephthalate) (PTMT) and its random and block copolymers with poly(tetramethylene isophthalate) (PTMI) and poly(tetramethylene oxide) (PTMO) is described. The differential scanning calorimetry heating scans of these polymers exhibit up to four endotherms. Endotherm I, the lowest-temperature endotherm, is an annealing peak and is ascribed to a clustering of PTMT sequences. Endotherms II, III, and IV are associated with crystal populations originated during periods of isothermal crystallization, cooling, and heating, respectively. The dependence of the endotherms on sample composition, crystallization and annealing temperatures, crystallization and annealing times, and sample cooling and heating rate is discussed. (Author abstract) 7 refs.

## Microscopic Examination

**081340 RUTHENIUM TETRAOXIDE STAINING TECHNIQUE FOR TRANSMISSION ELECTRON MICROSCOPY OF SEGMENTED BLOCK COPOLYETHERESTER.** Lamellar morphology of melt-crystallized polyetherester (PBT-PTMO) has been investigated by extending the technique of ruthenium tetroxide (RuO<sub>4</sub>) as a staining agent for the observation of the cast films using transmission electron microscope (TEM). The excellent image contrast obtained indicates that the RuO<sub>4</sub> staining technique is very effective and simple for the study of the lamellar structure of segmented block copolyetherester. (Author abstract) 6 refs.

## Microstructure

**081341 STRUCTURE AND PROPERTIES OF p-CARBOXYSUCCINANILIC POLYESTER RESINS.** Polyester resins were prepared by the reaction of p-carboxysuccinanic acid ethyl ester with ethylene glycol and 1, 4-butanediol. Also, unsaturated polyester resins were prepared by the copolymerization of p-carboxysuccinanic acid ethyl ester and maleic anhydride with ethylene glycol, 1,6-hexanediol, 1, 4-butanediol, and 2-butene-1,4-diol. All the polyester resins and the copoly-

esters have been characterized and were found to cure with styrene, except those prepared in the absence of maleic anhydride. The properties of the cured products in the form of films were determined. Infrared and nuclear magnetic resonance (NMR) spectroscopy were used for both qualitative and quantitative analyses of the polyester resins and their hydrolyzate products after curing with styrene. (Author abstract) 8 refs.

## Modification

**081342 TOUGHENED POLYESTER FOR BARRIER FILMS.** A new, patented technique to chemically toughen polyester (PET) has led to a new resin family that is close to amorphous PET in barrier properties. Selar PT can be heat sealed, and it provides enhanced elongation and better melt strength. The orientation step that is used to produce most PET film can thus be avoided. Given this unique combination of properties, Selar PT should find many applications in the packaging field as a cost-effective barrier film. Chemically toughened polyester resins have excellent heat sealability and can be used in blown and cast coextrusions.

**081343 CONFORMATIONAL CHARACTERISTICS OF AROMATIC POLYESTERS: COMPARATIVE STUDY OF THE POLARITY OF POLY(PROPYLENEGLYCOL TEREPHTHALATE) AND POLY(ETHYLENEGLYCOL TEREPHTHALATE).** Aromatic polyesters constitute a class of polymers having conformational characteristics strongly dependent on both the number of methylene groups of the glycol residue and the nature (terephthalic, isophthalic, phthalic) of the acid residue. The most prominent feature of the terephthalic and isophthalic acid-based polyesters is the coplanarity of the ester and phenyl groups. By substituting a methyl group for a hydrogen atom in the glycol residue of poly(ethyleneglycol terephthalate) (PET), an amorphous polyester, poly(propyleneglycol terephthalate) (PPT) is obtained, whose conformational properties differ from those of PET. Simple scrutiny of structural characteristics of PPT chains indicates that certain conformations that are accessible in PET are suppressed in PPT. In this work, the dipole moment of these chains and its temperature coefficient were measured and the results compared with those calculated using statistical mechanics. A comparative study of the polarity of PPT and PET was also made. 11 refs.

**081344 THERMOTROPIC POLYESTERS OF 4'-HYDROXYPHENYL-4-HYDROXYBENZOATE: A STUDY OF THE TRANSITION TEMPERATURES.** Polyesters based on 4'-hydroxyphenyl-4-hydroxybenzoate and dichlorides of dibasic acids, prepared using a high-temperature solution polycondensation in 1-chloronaphthalene, exhibit enantiotropic nematic mesomorphism. The range of temperatures for the nematic phase  $\Delta T_N$  can be controlled by changing the number of methylene units in the repeating polymer unit. For  $n=4$ ,  $\Delta T_N=97^\circ\text{C}$  is the largest that can be obtained. Higher  $n$  leads to smaller values of  $\Delta T_N$ . When  $n=12$ , the polyester exhibits only one single C-I transition. For  $n>12$  a smectic mesophase can be expected in this system. Strzelecki and Liebert reported a wide range of temperatures of  $\Delta T_N$  (70-160°C) for the Sn polymers made by the transesterification of 4'-acetoxyphenyl-4-acetoxybenzoate and the dicarboxylic acids. Authors believe the latter reaction occasionally involves the internal ester linkage in the monomer unit, producing a copolyester having a random distribution of hard segment lengths and changed

polymer mesomorphic properties. (Author abstract) 14 refs.

## Molecular Weight

**081345 MOLECULAR WEIGHT DISTRIBUTION MEASUREMENTS OF LIQUID CRYSTALLINE AROMATIC POLYESTERS BY GEL PERMEATION CHROMATOGRAPHY.** A GPC method was developed to measure molecular weight distributions (MWDs) of liquid crystalline aromatic polyesters (LCPs) which cannot be dissolved by ordinary organic solvents. The combination of pentafluorophenol (PFP) and polystyrene gel columns was found to give reproducible GPC curves of LCPs at 60°C by using a temperature-controlled instrument made at our laboratory. This GPC method revealed heretofore unrecognized features of the MWDs of LCPs: LCP-A, LCP-B, LCP-C (Fiber). GPC-LALLS method was utilized to make absolute molecular weight calibration curves for LCPs. (Author abstract). 5 Refs. In Japanese.

## Morphology

**081346 MORPHOLOGY OF POLYESTERS FORMED FROM SMECTIC LIQUID CRYSTAL.** The solid-state morphology of poly(hexamethylene p,p'-bibenzoate) (BB-6) and its dependence on the liquid-crystalline texture was studied by transmission electron microscopy. Thin films of BB-6 were prepared by casting a solution of the polymer in tetrabromoethane onto mica at 150°C. The temperature of the thin film was controlled on a hot-plate. The thin, liquid-crystalline films (210°C) which formed from the isotropic melt (260°C) were cooled gradually to room temperature. Long, plate-like structures composed of stacked lamellar crystals were formed in a thin film prepared from the thermotropic melt. An attempt was made to explain such a morphology in terms of Dupan's cyclide by assuming that a hyperbola in the cyclide is parallel to the surface of the BB-6 film. (Edited author abstract) In Japanese. 8 refs.

## Optical Properties

**081347 BIREFRINGENCE, THERMOELASTIC, AND DIELECTRIC STUDIES OF CYCLOALIPHATIC POLYESTERS.** Poly(diethylene glycol 1,4-trans-cyclohexanedicarboxylate) was synthesized by polycondensation of dimethyl 1,4-trans-cyclohexanedicarboxylate and diethylene glycol. The mean-square dipole moment  $\langle \mu^2 \rangle$  of the chains was measured in solutions of the polymer in benzene at several temperatures between 30 and 60°C. The experimental values of  $\langle \mu^2 \rangle$ , expressed in terms of the dipole moment ratio  $\langle \mu^2 \rangle / (\text{nm}^2)$ , changed from 0.588 to 0.608 in the temperature interval indicated above. Elastomeric networks were prepared by cross-linking of cycloaliphatic polyester with an aromatic triisocyanate. (Edited author abstract). 28 Refs.

Riande, E. (CSIC, Madrid, Spain); Guzman, J.; Campa, J.G. de la. *Macromolecules* v 21 n 7 Jul 1988 p 2128-2132.

## Permeability

**081348 TRANSPORT OF CARBON DIOXIDE AND METHANE IN GLASSY AROMATIC POLYESTERS.** Solubilities and diffusivities of  $\text{CO}_2$  and  $\text{CH}_4$  in aromatic polyesters generated from independent sorption and permeation measurements at 35°C and up to 25 atm, are compared. Less than 21% change in the glass diffusivity was observed. The data are interpreted qualitatively in terms of changes in the calculated packing density, chain torsional mobility of the polymer, and gas-polymer attraction. (Edited author abstract) 20 refs.

## Phase Transitions

**081349 DEPRESSIONS OF THE CRYSTAL-NE-MATIC PHASE TRANSITION IN THERMOTROPIC LIQUID CRYSTAL COPOLYESTERS.** The crystal-nematic phase transition of a copolyester consisting of 20 mol% poly(ethylene terephthalate) and 80 mol% p-hydroxybenzoic acid (PHB) was characterized by depression of the crystal-nematic transition by the addition of a liquid crystal diluent. This copolyester contains blocks of crystalline PHB. Its transition behavior was compared with that of a random copolyester with diluent of the same composition. From the extrapolated transition temperature depression data, the heat of transition per mole of p-oxybenzoate was calculated as about 1.3 kcal/mol, with an entropy of about 2 cal/deg mol. This assumes that only the p-oxybenzoate unit crystallized from the nematic state. The validity of the Flory-Huggins model for this transition point depression was confirmed graphically by comparison with two different thermotropic-liquid crystal polyesters. These results may represent the first reported crystal-nematic temperatures and heats generated by the dilution method for liquid crystal copolymers of this type. (Author abstract) 20 refs.

## Pressure Effects

**081350 PRESSURE-INDUCED PHASES IN A THERMOTROPIC POLYESTER.** In an effort to broaden the range of materials that might exhibit liquid crystallinity, we have examined the role of pressure on a copolyester of 20% hydroxybenzoic acid, 40% isophthalic acid, and 40% hydroquinone, 'HIQ-20', whose composition lies just inside of the mesophase range. This work was motivated by observations that low molar mass (isotropic) liquids may be transformed into mesophases at elevated pressures. The 'HIQ-20' thermotropic polyester is a rather complicated polymorphic system with high transition temperatures and narrow mesophase ranges. Additionally, this polyester exhibits a pressure-induced crystal phase. Generally speaking, these findings indicate that it may be possible to broaden the range of materials (copolyester composition) that will form mesogenic polymers: materials ruled out as candidates for liquid crystallinity at atmospheric pressures may be driven into ordered phases at elevated pressures. 18 refs.

**081351 CHAIN EXTENDERS FOR POLYESTERS. V. REACTIVITIES OF HYDROXYL-ADDITION-TYPE CHAIN EXTENDER; 2,2'-BIS(4H-3,1-BENZOXAZIN-4-ONE).** In a previous study, 2,2'-bis(4H-3,1-benzoxazin-4-one) (BNZ) was found to be the most effective among the tested chain extenders in coupling hydroxyl terminals of linear polyesters through addition reaction. Detailed studies on BNZ chemistry have been made using poly(ethylene terephthalate) and poly(butylene terephthalate) as the polyester. It has been observed that use of BNZ, equivalent amount to the hydroxyl terminals of the initial polymer, resulted in the highest molecular weight. In contrast with the case of 2,2'-bis(2-oxazoline), which was found to be the most effective carboxyl-addition type chain extender and a wide

range of its excess use was allowed, an excessive use of BNZ resulted in lower molecular weight polymer. Thus, when an equivalent amount of BNZ to the hydroxyl terminals was used, the molecular weight of the resulting polymer could be determined by the carboxyl content of the initial polymer, regardless of its initial molecular weight. (Author abstract) 8 refs.

**081352 ADDITIVES FOR OPEN-MOLD RP PROCESSES.** Air-release agents can reduce air inclusions by 60 to 90 percent in gelcoats and hand layup and achieve similar results in sprayup, filament winding, and pultrusion to improve processing and part quality. Wetting agents and styrene suppressants bring further improvements. A well-designed air-release agent should help prevent air entrapment during and after mixing. It should promote rapid air release so that all entrapped air can escape before gelling or setup occurs.

**081353 PREPARATION OF AROMATIC POLYESTERS OF HINDERED PHENOLS BY ACID-INTERCHANGE POLYCONDENSATION. 2. METAL SALT CATALYSIS.** The effect of the addition of metal salts as catalysts for the acid interchange polycondensation of tetrachlorobisphenol A diacetate with phthalic acids was examined. The acetate salts of some transition metals were found to have an effect upon the molecular weights of the polyesters produced, but inherent viscosities above 0.50 dL/g were not achieved with these catalysts. Modification of the nature of the salts by either the use of a mixture of acetate and strong acid anionic species, or by addition of an equivalent of strong acid to the metal acetate, to generate a mixed salt in situ, gave the most effective catalyst for the polycondensation. (Edited author abstract) 7 refs.

**081354 EFFECT OF CATALYST AND EMULSIFIER ON THE WATER CONTENT AND THE MECHANICAL PROPERTIES OF SOME WATER COMPOSITES.** Two unsaturated polyester resins were prepared and used to form stable emulsion prepolymers. Different emulsifiers were used to attain the optimal conditions of a stable emulsion. The stability of the emulsion were measured and the results were discussed, in relation to gelation time. Subsequent polymerization of the most stable emulsions by the use of styrene monomer, was studied in the presence of different types of catalysts in order to obtain water composites with improved mechanical properties. The water content of the cured composites was also studied. (Author abstract) 9 refs.

**Production** See Also PHOTORESISTS—Materials; THERMOPLASTICS.

**081356 SATURATED POLYESTERS (PET, PBT).** In the sector of thermoplastic polyesters, the last three years can be described as a period of application-oriented development of new materials. In competition with other engineering plastics, polyalkylene terephthalates are gaining increasing market shares. Whereas PET and PBT are similar in chemistry and commercially produced along the same principles, they differ in their processing techniques. Rapidly crystallizing PBT is an excellent injection moulding material for engineering applications, the less rapidly crystallizing PET is easier to stretch and is preferably extruded. The property profile of PET is similar to that of PBT and characterized by slightly higher mechanical data and a higher heat deflection temperature. Recent developments in the PET are copolyesters for transport applications with increased thermal stability. The chemistry and production process of PET and PBT also form the basis on which a variety of other polyesters are obtainable, e.g. thermoplastic polyester elastomers, polyacrylates and thermotropic 'liquid crystal' polyesters. PET and PBT are important components for polymer blends. 22 refs.

#### Pultrusion

**081357 DEVELOPMENT OF A MATHEMATICAL MODEL FOR THE PULTRUSION OF UNSATURATED POLYESTER RESIN.** A mathematical model is developed for simulating the pultrusion process of unsaturated polyester resin, using a mechanistic kinetic model based on free radical polymerization. In their previous publications, Han and Lee used the mechanistic model to simulate the curing behavior of unsaturated polyester resins under isothermal conditions, employing the differential scanning calorimetry data obtained for a range of single initiators and multiple initiator systems. For the sake of mathematical convenience, a pultrusion die of cylindrical geometry was considered. The mathematical model developed permits one to choose any number of initiators when predicting the distributions of the degree of cure and temperature in both the radial and axial directions of the die. (Edited author abstract) 8 refs.

#### Pyrolysis

**081358 A STUDY OF THE THERMAL DEGRADATION BEHAVIOUR OF POLYESTERS BASED ON HEXOLIC ANHYDRIDE.** The degradation behaviour of unsaturated polyesters containing hexolic anhydride has been studied. Pyrolysis experiments were performed using the TVA technique and the analysis of the products of pyrolysis was carried out utilising the gas chromatography-mass spectrometry technique. The formation of the various degradation products is discussed in the light of previously established mechanisms for polyester degradation. Special attention is devoted to a comparison of the present results on hexolic anhydride-based polyesters with previously studied HET-acid based polyesters, which are similar structural characteristics in the chlorinated part of the molecule. The major degradation product from the hexolic moiety is hexolic anhydride. The degradation products resulting from the 1,4-butanediol components are similar for both hexolic- and HET-based polyesters. Contrary to the HET-acid based systems, the hexolic-based polyesters yield considerably smaller quantities of hexachlorocyclopentadiene, which originates from the retro-Diels-Alder reaction. (Author abstract) 19 refs.

#### Radiation Damage

**081359 ELECTRON MICROSCOPY OBSERVATIONS OF A NEMATIC POLYESTER.** The authors report electron microscope observations of thin films of a polyester prepared in the nematic phase and quenched or slowly cooled. At low voltage (75 keV) the sample suffers irradiation damage and becomes amorphous in a few seconds. However, one observes the remnants of a striped structure. At high voltage (2000 keV) and low beam intensity the nematic structure is conserved, and the stripes consist of alternating disordered and aligned polymeric chains perpendicular to the striped structure. The repeat distance is on the order of a polymer length. Filamentary growth of a low temperature hexagonal phase is also reported. (Edited author abstract) 11 refs.

Mazelet, G. (Univ de Paris-Sud, Orsay, Fr); KJeman, M. *J Mater Sci* v 23 n 9 Sep 1988 p 3055-3060.

#### Recycling

**081360 RECYCLING OF POLYESTER FROM FABRIC WASTE.** This paper deals with the recycling of polyester (PET) from polymer cotton (P/C) blended fabric waste. For this purpose, the P/C waste, both carbonized and un-carbonized, is processed through a licker-in type opener. The fibers so obtained are characterized and hand spun to 10<sup>8</sup>-16<sup>8</sup> count. These yarns are used as weft and woven with 100 percent cotton warp on a hand loom. Suitable end uses have been suggested for these fabrics. Attempts have been made to produce adhesive bonded and needle punched non-wovens with these fibers. The work is in progress to recycle the PET and cotton by chemical/thermal dissolution techniques. (Author abstract).

#### Regain

**081361 FABRIC-CAUSED CHANGES IN HUMAN SKIN: IN VIVO STRATUM CORNEUM WATER CONTENT AND WATER EVAPORATION.** A focused microwave probe was used to assess stratum corneum water content, an Evaporimeter for water evaporation. With a covering of plastic film, water content and evaporation increased as the fabric/film remained on the forearm for longer periods of time. Stratum corneum water content was generally greater at polyester/film covered forearm sites than at triacetate/film covered sites, but there was not a significant statistical difference due to fabric type. Forearm water evaporation after fabric removal was also greater for polyester/film sites than triacetate/film sites; the difference was statistically significant. Occluded fabric placed on the skin surface therefore influences stratum corneum water content and water evaporation from its surface. (Edited author abstract) 35 refs.

**Reinforcing** See Also COMPOSITE MATERIALS—Fiber Reinforced; PLASTICS, REINFORCED—Fatigue.

**081362 CELLULOSE FIBER-POLYESTER COMPOSITES WITH REDUCED WATER SENSITIVITY (1) - CHEMICAL TREATMENT AND MECHANICAL PROPERTIES.** Formaldehyde and di-methylol-melamine were used to modify the surfaces of cellulose fibers. Composites were prepared with unsaturated polyester and treated cellulose as the reinforcing material. The tensile strength and the elongation of the cellulose fibers were determined in dry and wet conditions as well as the tensile strength and the tensile modulus of the cellulose-polyester composites. The water uptake of the composites was reduced by 46 to 52 percent. The wet strength of the composites was improved by more than 50 percent. (Author abstract) 16 refs.

Hua, Li (Chalmers Univ of Technology, Gothenburg,

Swed); Zadorecki, Pawel; Flodin, Per. *Polym Compos* v 8 n 3 Jun 1987 p 199-202.

**081363 CELLULOSE FIBER-POLYESTER COMPOSITES WITH REDUCED WATER SENSITIVITY (2) - SURFACE ANALYSIS.** The water absorption of cellulose fibers has been reduced after the cellulose surface was treated by mono- or di-methylolmelamine (DMM) resin. The wet strength of cellulose-polyester composites was also enhanced considerably. Scanning electron microscopy, transmission electron microscopy, and electron spectroscopy for chemical analysis were used as the tools for surface analysis in this study. The surface composition and micro morphology have been characterized. Quantitative and semiquantitative results have been obtained for the cellulose fiber surfaces treated with DMM. (Author abstract) 6 refs.

Hua, Li (Chalmers Univ of Technology, Gothenburg, Sweden); Flodin, Per; Ronnhult, Tore. *Polym Compos* v 8 n 3 Jun 1987 p 203-207.

**081364 USE OF EXTENDERS IN POLYESTER RESINS - A MATERIAL-SAVING CONCEPT OF PROCESSING GLASS FIBRE-REINFORCED POLYESTERS.** Preliminary tests revealed that the hollow-sphere fraction of the fly-ash from the Banhida Power-Station (BPH) Hungary, was suitable for preparation of syntactic polyester foams without any further purification or refinement. Morphological and physical studies on this BPH material as a filler of polyester resins are covered in this paper. The upper limit proportion of BPH was determined for the manual lamination technology. It was established by mechanical investigations on composites reinforced with glass mat or woven roving that a real sandwich structure with thickness of some millimeters could be formed in a single technological step. (Edited author abstract) 4 refs.

**081365 MECHANICAL AND DIELECTRIC RELAXATIONS IN CYCLOALIPHATIC POLYESTER NETWORKS.** Dielectric and mechanical loss tangent measurements performed on networks prepared from the cis (PCCS), trans (PTCS), and cis/trans (50/50, PCC) isomers of poly(oxyethylene-1,4-cyclohexylenemethyleneoxysebacoyl) present a well-defined  $\alpha$  absorption associated with the glass-rubber transition, whose location and strength depends on the presence of crystallites on the samples. The  $\alpha$  mechanical absorption at 1 Hz corresponding to amorphous PCCS and PCC networks is centered at  $-26^\circ\text{C}$  in both cases; however, the maximum of the peak is shifted to  $-17^\circ\text{C}$  for PTCS networks quenched from the melt. ## Rheology

**081366 ORGANOCLAY THICKENERS: ADVANCES IN TECHNOLOGY.** Advances in process technology have resulted in a new organoclay that exhibits a very open structure, plus high surface area and low density. With tailored chemical compatibility, it disperses readily enough in unsaturated polyester systems to permit incorporation as a dry powder, eliminating the need for preparing styrene pregs. The new material allows the full performance advantages of organonics because it is easily incorporated into the resin and is effective at low concentrations.

## Solutions

**081368 SALT EFFECTS ON CLOUD POINTS AND VISCOSITIES OF POLYMETHACRYLATES WITH PENDANT OLIGO-OXYETHYLENE CHAINS.** Comblike polymethacrylates with oligo-oxyethylene side chains were synthesized from the commercially available monomers  $\text{CH}_2=\text{C}(\text{CH}_3)\text{COO}(\text{CH}_2\text{CH}_2\text{O})_n\text{CH}_3$ , the average  $n$  being 4, 8, and 22. The three polymers exhibited lower critical solution temperatures in aqueous media. Cloud points were determined as a function of the nature and concentration of salt. For salts that destabilize the polymer solutions, the cloud points decrease linearly with salt concentration, the extent of the decrease being strongly anion dependent. Salt effects on the viscosity of the polymers were measured in water, methanol, and acetonitrile. In water the viscosity decreases on adding salt, but in methanol and acetonitrile the neutral polymers are converted to polycations as cations form stable adducts with the oligo-oxyethylene side chains. The increase in viscosity is both cation and anion dependent. The general behavior of the comblike polymers resembles that reported for aqueous or methanolic salt solutions of poly(ethylene oxide) and nonionic surfactants. (Author abstract) 46 refs.

## Spectroscopic Analysis

**081369 DETERMINATION OF ORDER PARAMETERS IN THERMOTROPIC AROMATIC POLYESTERS CONTAINING MESOGENIC AND FLEXIBLE FRAGMENTS IN THE MAIN CHAIN.** The order parameters of mesogenic ( $S_m$ ) and flexible ( $S_f$ ) fragments are determined for a range of aromatic thermotropic polyesters containing the same mesogenic and various flexible fragments in the main chain. The  $S_m$  values are almost independent of the chemical nature and length of the flexible spacer. The relative positions of the axes of the mesogenic and flexible fragments in various states of aggregation are determined. (Author abstract) 15 refs.

Volchek, B.Z.; Kholmuradov, N.S.; Purkina, A.V.; Bilibin, A.Yu.; Skorokhodov, S.S. *Polym Sci USSR* v 28 n 7 Jul 1987 p 1674-1682.

## Stresses

**081370 EFFECT OF PARTICULATE AGGLOMERATION AND THE RESIDUAL STRESS STATE ON THE MODULUS OF FILLED RESIN. PART 1. MODULUS OF UNTREATED GRADED SAND-FILLED Composite.** An untreated graded sand-filled polyester resin has been found to exhibit a higher modulus than previously reported for a particulate composite. A discontinuity in the stress-strain curve, which was dependent upon the volume fraction of sand, was observed. A residual stress mechanism is proposed to explain these results and the behavior of the composite at different curing temperatures. Fractography demonstrated the presence of trans-granular and inter-granular fractures. The former confirmed the presence of a strong matrix-particle interface bond even though the latter could only be explained by the expected poor 'chemical' adhesion in the

absence of a coupling agent. These apparent contrasting results are considered to arise from the presence of residual compressive stresses around agglomerates of irregularly shaped particles. (Author abstract) 20 Refs.

**081371 CHOLESTERIC LIQUID CRYSTALLINE POLYESTERS. 1. CHOLESTERIC LIQUID CRYSTALLINE COPOLYESTERS BASED ON POLY(CHLORO-1,4-PHENYLENE TRANS-1,4-CYCLOHEXANEDICARBOXYLATE).** Thermotropic copolymers exhibiting cholesteric mesophases were prepared by introducing chiral (R)-3-methyladipate units into rigid poly(chloro-1,4-phenylene trans-1,4-cyclohexanedicarboxylate), and a morphology study of the solid cholesterics was examined by using a transmission electron microscopy method. The transmission electron micrographs showed a series of dark and bright striation lines which were attributed to the periodic structure of the cholesteric helix. Defects or imperfections such as disclinations and edge dislocations of the cholesteric layer texture were elucidated from the micrographs. These cholesteric copolymers were also characterized by DSC, spectroscopic, and optical microscopic methods. (Edited author abstract) 26 refs.

**081372 LIGHT SCATTERING STUDY OF POLYPHENYLHYDROQUINONE-CO-TEREPHTHALIC ACID.** The above wholly aromatic polyester, poly(phenylhydroquinone-co-terephthalic acid) is studied by differential scanning calorimetry, and dilute solutions of fractions are examined by static and dynamic light scattering techniques. This polyester has two crystal modifications and exhibits a thermotropic nematic phase over the temperature range  $350-450^\circ\text{C}$ . Values for the persistence length calculated by three methods range from 60 to 150 Angstrom, with an average of 100 Angstrom. Space-filling models indicate that the substituent phenyl group prevents the benzene ring and the adjacent carbonyl group from being planar, which may explain the small persistence length. (Edited author abstract) 43 refs.

**081373 SOLID-STATE CROSS POLARIZATION/MAGIC ANGLE SPINNING  $^{13}\text{C}$  NMR STUDY OF THERMOTROPIC AROMATIC POLYESTER CONTAINING A FLEXIBLE SPACER IN THE MAIN CHAIN.** The solid-state structure of a thermotropic aromatic polyester containing an aliphatic flexible spacer based on terephthalic acid and 4,4'-dihydroxy-1,6-diphenoxyhexane has been investigated by high-resolution solid-state CP/MAS (cross polarization/magic angle spinning)  $^{13}\text{C}$  NMR. Samples of the polymer with different thermal histories, i.e., an original sample as obtained by low-temperature solution polymerization and once-melted samples with different cooling conditions have been prepared. For the original sample, the solid-state spectrum shows that a conformation of the hexamethylene spacer is all-trans in the plane of the phenoxy group and that the ester linkage is nearly perpendicular to the plane of the aromatic ring. (Edited author abstract) 33 refs.

**081374 TWO-DIMENSIONAL NMR AND PROTON SPIN-LATTICE RELAXATION STUDIES OF THERMOTROPIC HOMOPOLYESTERS CONTAINING A BICYCLO[2.2.2]OCT-2-ENE RING SYSTEM.** In this paper, we describe the detailed proton nuclear magnetic resonance, homonuclear two-dimensional shift correlation (COSY) and proton spin-lattice relaxation studies to determine the structures of homopolymers. The proton NMR spectrum of homopolymer II in deuteriotrifluoroacetic acid is shown. It is of interest to note that the olefinic protons of bicyclo[2.2.2]oct-2-ene appear as a singlet and also as a double doublet centered at  $\delta$  6.45. The fact that the doublet centered at  $\delta$  6.55 is coupled to the doublet centered at  $\delta$  6.34 is confirmed by a two-dimensional shift correlation experiment. This suggests that there are two sets of vinyl protons, one being equivalent ( $\delta$  6.64) and the other being nonequivalent. 31 refs.

**081375 HYDROGEN-BONDED HIGHLY REGULAR STRICTLY ALTERNATING ALIPHATIC-AROMATIC LIQUID-CRYSTALLINE POLYESTER AMIDES.** Forty-seven highly regular strictly alternating poly(ester amides) typified by each aromatic ring being bracketed by several methylene groups were prepared and studied. It was found that when the methylene sequences were sufficiently long, the poly(ester amides) exhibited multiple reproducible first-order transitions upon heating, which did not all reappear upon cooling. Many of the polymers with long alkylene groups grew ordered batonnet-like structures upon cooling from the isotropic melt, but not upon heating. The ordered structures grew upon cooling at temperatures far higher than the uppermost major endotherm in the heating cycle. A combination of DSC and hot-stage cross-polarized light microscopy revealed, upon heating, broad temperature intervals where spontaneous flow and intense or dull birefringence coexisted. (Edited author abstract). 68 refs.

**081376 NEW THERMOTROPIC HOMO- AND COPOLYESTERS CONTAINING  $\alpha$ ,  $\alpha'$ -DIETHYLSTIBENE AS A MESOGEN.** New thermotropic homo- and copolymers (IV) have been prepared from 4,4'-dihydroxy- $\alpha$ , $\alpha'$ -diethylstilbene (I) and aliphatic diacid chlorides (adipoyl and sebacoyl chlorides) [(II) and (III)] by interfacial polycondensation, and their liquid crystallinity was evaluated. The mesogenic properties of homo- and copolymers were investigated by the observation of texture by means of a polarizing microscope equipped with hot stage and with DSC. The maximum temperatures of endothermal peaks in DSC curves on a first heating run were taken as phase-transition temperature. It is found that the introduction of longer alkyl chain into  $\alpha$ , $\alpha'$ -position lowers the phase-transition temperatures of stilbene-type polymers and widens their mesophasic ranges, although the molecular weight and the wide molecular-weight distribution of the polyesters may affect the liquid crystalline behavior. 12 refs.

## Synthesis See Also POLYMERIZATION.

**081377 THERMOTROPIC POLYESTERS: SYNTHESIS AND PROPERTIES OF POLY(CHLORO-1,4-PHENYLENE TEREPHTHALATE-CO-4,4'-OXYBISBENZOATES).** Poly(chloro-1,4-phenylene terephthalate), poly(chloro-1,4-phenylene 4,4'-oxybisbenzoate), and their copolymers are synthesized and the effect of composition on thermal transitions is evaluated. All the materials are nematogenic; copolymer compositions from 75/25 to 25/75 display a nematic temperature range in excess of 100°C which is sufficient for melt processing. The crystal-nematic transition temperature of the 50/50 copolymer is strongly affected by the molecular weight, but the glass transition, although low,

is molecular weight independent. Brief annealing at temperatures below the crystal-nematic transition does not reduce the nematic temperature range of this copolymer. (Author abstract) 18 refs.

**081378 SYNTHESIS AND CHARACTERIZATION OF POLYESTERS CONTAINING HETEROCYCLIC THIAOXANTHONE UNITS.** Several polyesters containing thiaoxanthone rings were prepared from 2,7-dichloroformylthiaoxanthone-5,5'-dioxide (IVa), 2,8-dichloroformylthiaoxanthone-5,5'-dioxide (IVb), and bisphenols by solution polycondensation. The 2,8-diethoxycarbonylthiaoxanthone-5,5'-dioxide (V) was prepared and characterized by spectral methods to confirm the formation of 2,8-thiaoxanthonedicarboxylic acid-5,5'-dioxide (IVb). Prior to polymer synthesis two model compounds, 2,7-diphenoxycarbonylthiaoxanthone-5,5'-dioxide (MDE-1) and 2,8-diphenoxycarbonylthiaoxanthone-5,5'-dioxide (MDE-2), were synthesized and characterized by spectral methods. The polyesters were obtained in 62-78% yield and had inherent viscosities in the range 0.42-0.90 dL/g. The effect of thiaoxanthone rings on solubility, crystallinity, and thermal stability of the polyesters are also discussed. The polyesters have decomposition temperatures in the range 372-438°C. (Author abstract) 18 refs.

**081381 DIRECT POLYESTERIFICATION WITH THIONYL CHLORIDE IN PYRIDINE IMPROVED BY A MODIFICATION OF MONOMER SEQUENCES IN COPOLYMERS.** The direct polyesterification with thionyl chloride (SOCl<sub>2</sub>) in pyridine was investigated. Copolycondensations of dicarboxylic acids, bisphenols, and hydroxybenzoic acids were significantly affected by the reaction temperatures and combinations of monomers which could change relative rates of alcoholyses of the activated dicarboxylic acids and the hydroxyacids consequently to vary monomer sequences in the copolymers resulted. The sequences were varied more directly by stepwise reactions of monomers in copolycondensations of dicarboxylic acids, bisphenols, and p-hydroxybenzoic acid (PHB), as well as PHB and m-hydroxybenzoic acid

(MHB). The reactions proceeded smoothly and satisfactorily when carried out by initial reaction of dicarboxylic acids and PHB followed by bisphenols likely to favor sequential to random distributions of monomers. (Edited author abstract) 8 refs.

**081382 LINEAR POLYESTERS PRODUCTS OF INTERFACIAL POLYCONDENSATION OF BIS(4-HYDROXYPHENYL)ETHER WITH SOME ALIPHATIC ACID DICHLORIDES.** New polyesters were obtained by interfacial polycondensation of bis(4-hydroxyphenyl)ether with succinyl, adipoyl, suberoyl, or sebacoyl chlorides. To define the optimal conditions of the process, the polyesters of diol and adipoyl or sebacoyl chlorides were chosen as a model system. Yield for all reaction products and reduced viscosity were found. The following factors were studied: organic phase, contribution of catalyst, concentration and molar ratio of reagents, rate of addition of acid chloride, temperature of reaction and concentration of hydrochloride acceptor. The structures of all polyesters were determined by means of elementary analysis, infrared spectra, and X-ray. Initial decomposition and initial intensive of decomposition temperatures were defined by the curves of thermogravimetric analysis. Thermal and electrical properties of polyesters from diol and adipoyl or sebacoyl chlorides were studied. The molecular weights for these polymers were also determined by gel chromatography. (Edited author abstract) 8 refs.

**081384 CONDENSATION POLYMERIZATION OF MULTIFUNCTIONAL MONOMERS AND PROPERTIES OF RELATED POLYESTER RESINS. I. POLYESTER VARNISHES.** This article discusses optimum conditions for polycondensation of multifunctional monomers. Reaction variables such as monomer concentration, temperature, and time were studied to optimize reaction conditions. The influence of the nature and concentration of catalysts was also investigated. Polycondensation of ethylene glycol, 1,4-butanediol, pentaerythritol, and trifunctional monomers (glycerin or trimethanolpropane) with dimethyl terephthalate was carried out in m-cresol to produce polyester prepolymers. The synthesized prepolymers were mixed with commercial Desmodur CT-stable (a phenol-blocked polyisocyanate) to form one-component varnishes which were characterized by thermogravimetric analysis. Polyester modified with trimethanolpropane has higher thermal stability than the one modified with glycerin. After being coated onto treated copper wires, the magnetic wires were character-

ized according to the specification of Japanese Industrial Standards (JIS-C-2538) and were found to be acceptable. (Edited author abstract) 8 refs.

Chiang, Wen-Yen (Tatung Inst of Technology, Taipei, Taiwan); Chiang, Wen-Chang. *J Appl Polym Sci* v 35 n 6 May 5 1988 p 1421-1432.

**081385 CONDENSATION POLYMERIZATION OF MULTIFUNCTIONAL MONOMERS AND PROPERTIES OF RELATED POLYESTER RESINS. II. THERMAL PROPERTIES OF POLYESTER-IMIDE VARNISHES.** Polyester-imide prepolymers containing synthesized N,N'-bis(hydroxyethyl)pyromellitic diimide (PMDI) or N,N'-bis(hydroxyethyl)-3,3',4,4'-benzophenone tetracarboxylic diimide (BTDI) were synthesized under conditions previously reported. One-component varnishes were obtained by mixing the synthesized prepolymers with commercial Desmodur CT-stable. Thermal behavior of these varnishes was investigated using thermogravimetric analysis. Activation energy of cured film, which was a polyester-imide varnish, was determined by using a multiple heating rate method. Polyester-imides coated copper wires were characterized, and were found to be acceptable, according to the specification of Japanese Industrial Standard (JIS-C-3214). (Author abstract) 10 refs.

**081389 CATIONIC RING-OPENING ISOMERIZATION POLYMERIZATION OF BICYCLO ORTHO ESTERS INITIATED BY CARBON BLACK.** The cationic ring-opening isomerization polymerization of bicyclo ortho esters (BOE) initiated by carbon black was investigated. The polymerization scarcely proceeded in the absence of carbon black. But in the presence of channel black having carboxyl groups, the polymerization of BOE was initiated at 130°C to give a polyether containing an ester group in the side chain. The initiating ability of carbon black increased with increase in its carboxyl group content. Furnace black having no carboxyl group was unable to initiate the polymerization. Based on these results, it was concluded that the carboxyl group on carbon black is capable of initiating the polymerization of BOE. During the polymerization, a part of the polymers formed was grafted onto carbon black via the termination of growing polymer chain. Furthermore, the ring-opening isomerization polymerization of BOE was found to be initiated by an acylium perchlorate group introduced onto the carbon black surface. (Edited author abstract). 22 Refs.

**081390 ISOCYANATE TECHNOLOGY SPAWNS NEW BREED TPE FOR HIGH TEMPERATURES.** For the synthesis of the polyesteramide (PESA) a process was developed based on isocyanate technology, wherein the isocyanate was reacted with carboxylic acids to yield amide plus carbon dioxide. Variations in properties could be achieved by varying the type of soft segment-polyether, or polyester, and the amount of soft segment vs. hard segment. PESA can be processed readily on conventional thermoplastic processing equipment; however, it must be thoroughly dried to a moisture content of less than 0.02 percent. This is accomplished in a dehumidifying hopper dryer at 100-110°C for 4 to 6 hours. PESA exhibits outstanding chemical resistance and is relatively unaffected by ASTM oils, greases and transmission fluids, or dilute acids and bases. Some swelling is observed in alcohol and aromatic solvents. In part because of its aromatic amide backbone, PESA exhibits outstanding resistance to ultraviolet radiation. 3 Refs.

**081391 NEW POLYMER SYNTHESIS. 24. LIQUID CRYSTAL POLY(ESTER IMIDES) DERIVED FROM BENZOPHENONETETRACARBOXYLIC DIANHYDRIDE AND  $\omega$ -AMINO ACIDS.** Six dicarboxylic acids were prepared from benzophenone-3,3',4,4'-tetracarboxylic dianhydride (BTA) and 4-amino-butyric acid, 5-aminovaleric acid, 6-aminocaproic acid, 7-aminoheptanoic acid lactam, 11-aminoundecanoic acid, and 12-aminododecanoic acid. These diacids were condensed with the diacetates of hydroquinone, 2,6-dihydroxynaphthalene or 4,4'-dihydroxybiphenyl. The resulting poly(ester imides) were characterized by inherent viscosity elemental analyses, differential scanning calorimetry (DSC), observation under polarized light, and WAXS measurements. Formation of a smectic melt was found for almost all polymers containing 4,4'-dihydroxybiphenyl. These thermotropic poly(ester imides) were also characterized by thermomechanical and thermogravimetric analyses, and an odd-even effect was found for the heat-distortion temperatures. (Edited author abstract). 11 Refs.

**081392 POLYMORPHISM IN A LIQUID CRYSTALLINE POLYESTER BASED ON 4, 4'-BIPHENOL, TEREPHTHALIC ACID, AND p-HYDROXYBENZOIC ACID(1:1:2).** The polyester from 1 mol of 4,4'-biphenol, 1 mol of terephthalic acid, and 2 mol of p-hydroxybenzoic acid, synthesized by the acidolysis condensation reaction of the acetylated mixture, was

studied by using wide-angle X-ray diffraction and differential scanning calorimetry (DSC). X-ray diffraction demonstrated a reversible crystal-crystal transition at about 100°C. The transition was also observed with DSC as a small endotherm. The most prominent calorimetric feature is an endotherm at about 427°C corresponding to the crystal-nematic transition. There is also a small endotherm at about 472°C which may correspond to the nematic-isotropic transition. On cooling from 450°C at 10 deg/min, there is observed about 40 deg of supercooling before crystallization occurs. (Edited author abstract). 12 Refs.

Field, N.D. (Dartco Manufacturing Inc, Augusta, GA, USA); Baldwin, R.; Layton, R.; Frayer, P.; Scardiglia, F. *Macromolecules* v 21 n 7 Jul 1988 p 2155-2160.

**081394 THERMAL BEHAVIOR OF THE SMECTIC/NEMATIC THERMOTROPIC LIQUID CRYSTALLINE POLYESTER BLENDS.** Crystalline and liquid crystalline behavior of the mesogenic binary blends consisting of smectic and nematic liquid crystal polyesters were investigated by differential scanning calorimetry and by polarizing microscope. The blends did not form eutectic mixture and the homopolymers were partially miscible in the solid state. The liquid crystalline phase of the blend showed coexisting nematic and smectic phases at a certain composition. (Author abstract)

Yoo, Young Deuk (Korea Advanced Inst of Science & Technology, Seoul, South Korea); Kim, Sung Chul. *Polym Bull (Berlin)* v 18 n 3 Sep 1987 p 247-252.

**081395 THERMAL PROPERTIES OF A SERIES OF SIDE-CHAIN LIQUID CRYSTALLINE POLY(METHACRYLATES).** The thermal behavior of a series of side-chain liquid crystalline poly(methacrylates) has been investigated by thermogravimetry, differential scanning calorimetry, polarizing optical microscopy, and dilatometry. The DSC study has shown that long times are required to reach equilibrium even at temperatures above the glass transition. The thermotropic polymorphism has been determined as a function of the length of the flexible spacer. Glass transitions in the mesomorphic state have been discussed. Dilatometry has shown that, for the 'glassy' mesomorphic phases, the partial specific volume of the flexible spacer is close to that corresponding to the crystal and the isotropic liquid; and that, for the isotropic polymer, it is close to that of a liquid. (Author abstract) 22 refs.

## Viscoelasticity

**081397 EFFECTS OF PHYSICAL AGING ON THE VISCOELASTIC BEHAVIOR OF A THERMOSET POLYESTER.** The effect of physical aging on the viscoelastic behavior of a cross-linked polyester resin is reported. Tensile creep and dynamic mechanical analysis (DMA) tests yielded creep compliance and dynamic shear complex compliance of the polymer. Thermoreversible physical aging was found to have significant effects in the creep response of the polyester. Physical aging shift factors were determined at 60, 80, 100 and  $120^\circ\text{C}$ . Standard frequency-temperature superposition procedures were used to construct master curves or the dynamic mechanical data. The shift constants  $c_1=(70)$  and  $c_2=(450^\circ\text{C})$  determined from DMA data were used to construct a smooth master curve for creep data. (Edited author abstract) 22 refs.

**081398 DYNAMIC MECHANICAL RELAXATIONS OF POLYTEREPHTHALATES BASED ON TRIMETHYLENE GLYCOLS.** The dynamic mechanical relaxations of poly(trimethylene glycol terephthalate) (PTMT), poly(ditrimethylene glycol terephthalate) (PDMT) and two copolymers obtained from them have been studied between  $-150$  and  $200^\circ\text{C}$  with a dynamic viscoelastometer. The four polymers show three relaxations that are designated  $\alpha$ ,  $\beta$ , and  $\gamma$  in order of decreasing temperature. The  $\alpha$  relaxation is considered to be the glass transition of the polymers. The  $\beta$  relaxation is wider and weaker than the  $\alpha$ , as normally occurs in the polyester series. The  $\gamma$  relaxation takes place at temperatures below  $-100^\circ\text{C}$  and is usually overlapped by the  $\beta$  relaxation. The influence of thermal and mechanical histories on the nature, location, and intensity of the three relaxations is studied and discussed. (Author abstract) 19 refs.

## POLYETHERIMIDES

### Applications

**081399 EFFECTS OF FLUIDS IN THE AIRCRAFT ENVIRONMENT ON A POLYETHERIMIDE.** Fluid absorption studies have been made for a polyetherimide thermoplastic film and a unidirectional composite of the thermoplastic with graphite fibers immersed in water, JP4 jet fuel, ethylene glycol, and hydraulic fluid. The changes in the weight, thickness, and tensile properties were measured for the film. The changes in the flexural properties of the composite were measured for specimens whose fiber orientation was transverse to their length. Only the hydraulic fluid, which caused an erosion or dissolution of the resin at the specimen surface, affected

the film's properties. Both the water and the hydraulic fluid affected the flexural properties of the composite, due to capillary absorption along the fiber-resin interface. (Edited author abstract) 9 refs.

### Aging

**081400 PHYSICAL AGING CHARACTERISTICS OF POLYETHER ETHER KETONE.** Creep studies and differential scanning calorimetry (DSC) indicate that physical (thermal) aging affects viscoelastic properties of polyether ether ketone (PEEK) at all achievable levels of crystallinity. The phenomenon has been observed over a range of crystallinity (2%-33% by volume) at several test temperatures. When the glass transition temperature ( $T_g$ ) are different, even for the same undercooling ( $T_g-T$ ), the parameters are significantly different. Dependence of enthalpy relaxation on aging time was obtained from DSC thermograms for the amorphous polymer. (Edited author abstract) 18 refs.

**081401 HEMOLYTIC ACTIVITY OF POLYOXYETHYLENE CHOLESTERYL ETHERS.** Hemolytic activity of nonionic surfactants, polyoxyethylene cholesteryl ethers,  $\text{C}_{27}\text{H}_{45}\text{O}(\text{CH}_2\text{CH}_2\text{O})_n\text{H}$  (Chol- $E_n$ ,  $n = 8, 25, 30, 50$ ) and polyoxyethylene dihydrocholesteryl ethers,  $\text{C}_{27}\text{H}_{47}\text{O}(\text{CH}_2\text{CH}_2\text{O})_n\text{H}$  (DHChol- $E_n$ ,  $n = 15, 30, 50$ ) were measured, changing the concentration of surfactant and erythrocyte at  $37^\circ\text{C}$ . Maximum hemolytic activity was observed in these cholesteryl derivatives with 25-30 oxyethylene units. The time course of hemolysis was also measured as a function of the concentrations of surfactant and erythrocyte. Hemolysis started after a certain induction period,  $\tau$ , and then apparently proceeded as a first-order reaction with respect to the erythrocyte concentration. The surfactant inducing 50% hemolysis at low concentration had a small  $\tau$  value and large rate constant. The maximum amount of adsorption without inducing hemolysis,  $a_0$ , decreased with increasing polyoxyethylene chain length. Chol- $E_{25}$  has the maximum activity for the solubilization of egg yolk lecithin at  $37^\circ\text{C}$ . Based on these results, the mechanism of hemolysis by these surfactants was quantitatively discussed. (Author abstract) 23 refs.

### Deformation

**081403 PLASTIC DEFORMATION OF POLYTETRAMETHYLENE OXIDE. I. INFLUENCE OF MOLECULAR WEIGHT DISTRIBUTION, CRYSTALLINITY, AND STRUCTURE.** Polytetramethylene oxide with a planar zig-zag structure similar to polyethylene can be obtained with narrow molecular weight distributions. The plastic deformation of samples differing in molecular weight, molecular weight distribution, crystallinity, and structure has been studied. The low natural draw ratios and low Young's modulus of the drawn samples, together with the effect of blending a small amount of high molecular weight material into a low molecular weight sample, highlight the role of the flexibility and of the high molecular weight tail of the distribution in the plastic deformation process. The stress required for the propagation of the neck and the tensile strength are found to be linear functions of, respectively, the natural and maximum draw ratio. (Edited author abstract) 23 refs.

**081405 ROTATING FRAME PROTON SPIN-LATTICE RELAXATION MEASUREMENTS OF POLY(ETHYLENE OXIDES).** Recently the technique of measuring spin-lattice relaxation times  $T_{1\rho}$  in the rotating frame has been used widely for the investigation of molecular motion and phase changes in a variety of solid materials, including polymers. In this work, measurements of  $T_{1\rho}$  as a function of temperature have been made on two polyethylene oxides (PEO) with molecular masses of 5,000 and 30,000. The  $T_{1\rho}$  measurements show biexponential behavior of the relaxation function in the temperature range from 170 K to 350 K. The intensities of the components of the relaxation function are constant over this temperature range in agreement with the crystallinity

ties of the samples. The two relaxation times can be associated with the crystalline and amorphous component; the relaxation time mining describe the  $\alpha$  relaxation in the crystalline regions of PEO and the glass transition in amorphous PEO. (Edited author abstract) 7 refs.

## Physical Properties

**081406 INFLUENCE OF LiClO<sub>4</sub> ON THE PROPERTIES OF POLYETHER NETWORKS: SPECIFIC VOLUME AND GLASS TRANSITION TEMPERATURE.** A series of networks based on different polyether chains (PEO homopolymer, block and graft copolymers) joined by different urethane cross-links were prepared. Their specific volume and  $T_g$  were determined in the absence and in the presence of LiClO<sub>4</sub> as a function of various structural parameters and of salt concentration. Quantitative correlations were obtained and interpreted on the basis of specific interactions between the ether groups and the ionized salt. Chain partitioning and physical cross-linking occurred as a consequence of these associations. (Author abstract) 9 refs.

## Reduction

**081407 TRI-N-BUTYL TIN HYDRIDE REDUCTION OF THE END GROUP OF A POLYPHENYLENE ETHER.** A method using tri-n-butyltin hydride to reduce the 2-methyl-6-(N,N-di-n-butylamino)methyl phenol end group on PPO (4) was developed. It generated a polyphenylene ether (PPE) with 2,6-xylenol as the only phenolic end group without causing any significant increase in molecular weight. The reduction was carried out in diphenyl ether under nitrogen overnight at 250°C. The reduced PPE was collected and dried. A control experiment was also conducted. (Edited author abstract) 9 refs.

**Solutions** See Also CELLULOSE DERIVATIVES—Physical Chemistry.

**081408 VISCOSITY B COEFFICIENTS OF POLYETHYLENEGLYCOLS IN WATER.** The viscosity B coefficients of polyethylene glycols ( $M = 62-1000$ ) are determined at 25 °C. The B coefficient increases non-linearly with the number of ethyleneoxide (EO) units. The increase of the B coefficient per EO (0.111 dm<sup>3</sup>/mole) is less than the B value for two methylene groups (0.160 dm<sup>3</sup>/mole). This is discussed in terms of changes in the configurations of polyethylene glycols with long EO chains. Molecular size is the major factor that contributes to B at shorter chains, but solvation (hydration) becomes dominant as the number of ethyleneoxide groups increases. The hydration parameter shows a linear dependence on B at low mass followed by a non-linear increase at high molecular mass and the viscosity C coefficient accounts for the solute-solute interactions. (Author abstract) 28 refs.

**081409 SYNTHESIS AND PROPERTIES OF NON-CYCLOC POLYETHER COMPOUNDS. XV. NONCYCLIC POLYETHER CARRIERS EXHIBITING POTASSIUM-ION-SELECTIVE TRANSPORT THROUGH LIQUID MEMBRANES: THEIR**

**STRUCTURES AND CATION SELECTIVITY.** The effects of the structure of noncyclic polyethers on potassium-ion-selective transport have been investigated using several synthetic noncyclic polyethers as carriers for transport through liquid membranes. The K<sup>+</sup> selectivity of a polyether with an oxytrimethylene group instead of an oxyethylene group decreased significantly. The position of the introduced o-phenylene group affects the cation selectivity of the polyethers. A polyether with a quinolyl terminal group exhibits superior K<sup>+</sup> selectivity to otherwise identical polyethers with naphthyl or n-butyl terminal groups. (Edited author abstract) 18 refs.

## Suspensions

**081410 DEFORMATION OF VISCOUS DROPLETS IN AN ELECTRIC FIELD: POLY(PROPYLENE OXIDE)/POLYDIMETHYLSILOXANE SYSTEMS.** Deformation of droplets in an alternating electric field of 60 Hz was investigated for drops of poly(propylene oxide) (PPO) and water suspended in poly(dimethylsiloxane) (PDMS). Under a low field strength E, the droplet deformed into an ellipsoid. The equilibrium shape and the rate of deformation were analyzed in terms of the degree of deformation. Under a strong field, drops became unstable and were elongated to a thin thread or bursted into fine droplets. We classified these burst behaviors into four classes. (Edited author abstract) 18 refs.

**081413 FUNCTIONAL POLYMERS AND SEQUENTIAL COPOLYMERS BY PHASE TRANSFER CATALYSIS. XXVI. SYNTHESIS AND CHARACTERIZATION OF THERMOTROPIC LIQUID CRYSTALLINE POLYPODANTS.** Thermotropic liquid crystalline (LC) polyethers and copolymers have been synthesized from 4,4'-dihydroxy- $\alpha$ -methylstilbene (HMS) and  $\alpha,\omega$ -dichlorooiligo(oxyethylene)s having between 2 and 5 as well as 8.7 oxyethylene units. Copolyethers were prepared from a 1:1 mol/mol ratio of two dissimilar spacers. These polymers have been prepared by a phase transfer catalyzed (PTC) polyetherification of bisphenols with these electrophiles by utilizing 50 mol% tetrabutylammonium hydrogen sulfate per phenol group. Kinetic experiments with either 5 or 50 mol% catalyst vs phenol groups in the polyetherification of 4,4'-isopropylidenediphenol with 2-chloroethyl ether have shown that a change in catalyst primarily affects the rate of reaction, with 50 mol% being faster. (Edited author abstract) 46 refs.

## Thermal Expansion

**081414 THERMAL EXPANSION OF POLYOXYMETHYLENE.** The thermal expansivities of polyoxymethylene crystals in the direction parallel and perpendicular to chain axis have been measured from 160 to 400 K using wide-angle X-ray diffraction. Although polyoxymethylene has a helical chain structure, it exhibits a thermal expansion behavior similar to that of polymer crystals with planar zigzag chains. The thermal expansivity is found to vary linearly with crystallinity, thus allowing the expansivity of the amorphous phase to be derived by extrapolation. With the thermal expansivities of the crystalline and amorphous phases known, the draw ratio dependence can be calculated in terms of existing models and is found to agree reasonably with experimental data. (Edited author abstract) 26 refs.

**Thermal Properties** See ALKALI METAL COMPOUNDS—Thermal Properties.

## Thermodynamic Properties

**081415 PRESSURE-VOLUME-TEMPERATURE RELATIONSHIP AND THE HEAT OF FUSION OF POLYOXYMETHYLENE.** The pressure-volume-temperature relation of polyoxymethylene was measured at pressures from 100 to 2000 kg/cm<sup>2</sup> and from room temperature to 220°C. The dependence of the melting and crystallization temperatures on pressure was also determined. The unit cell parameters were measured up to 170°C by x-ray diffraction. These data were combined through the use of the Clapeyron equation to compute a heat of fusion of 92.9 cal/g. This value is considerably higher than those previously reported. The weight fraction crystallinity of an injection molded sample was 48% by calorimetry and 66% by interpolation between the specific volumes of the crystal and the amorphous phase. It is suggested that a simple two-phase model is inadequate to describe this polymer. (Author abstract) 19 refs.

Starkweather, Howard W. Jr. (DuPont, Wilmington, DE, USA); Jones, Glover A.; Zoller, Paul. *J Polym Sci Part B* v 26 n 2 Feb 1988 p 257-266.

**081416 EFFECT OF CRYSTALLINITY ON THE EXCIMER FLUORESCENCE OF POLY(ETHYLENE TEREPHTHALATE) FILM.** An increase in the intensity ratio of the monomer-to-excimer fluorescence with crystallinity has been found in semicrystalline poly(ethylene terephthalate) films, while in the amorphous film the emission was almost exclusively from excimers. This is easily understandable as the molecular packing in the crystalline lattice precludes excimer formation. From morphological considerations we are led to the conclusion that the range of energy migration must be much shorter than ca. 10 nm. (Edited author abstract) 9 refs.

**081417 MEASUREMENT OF THE MELTING POINTS OF OLIGOMERS OBTAINED IN THE MANUFACTURE OF POLY(ETHYLENE TEREPHTHALATE).** The melting points ( $T_m$ ) were measured for oligomers obtained by a direct continuous esterification process between terephthalic acid and ethylene glycol. Multiple regression analyses of data were carried out, and an equation was obtained for predicting melting points with correlation coefficient of approx. 0.99. (Author abstract) 3 refs.

Yamada, T. (Toyobo Co, Shiga, Jpn); Mizuno, Y.; Imamura, Y. *Polym Eng Sci* v 28 n 6 Mar 1988 p 377-380.

**081418 RELATION BETWEEN CHARACTERISTICS AND MELTING POINT OF OLIGOMERS IN POLY(ETHYLENE TEREPHTHALATE) MANUFACTURING.** The applicable range of the regression equation proposed by Yamada, et al. expressing oligomer melting point by oligomer characteristics and relations derivable from the equation correlating each oligomer characteristic and melting point were studied. It was confirmed that the equation is applicable not only to poly(ethylene terephthalate) (PET) oligomer but also to the extent of polymerization. As number-average degree of polymerization ( $P_n$ ) increases, the influence of end groups on melting point becomes weak, and when  $P_n$  exceeds 50, the influence of end groups becomes negligibly small. On the other hand, when  $P_n$  is below 2, it was confirmed that the influence of end groups on melting point is very strong. (Author abstract) 6 refs.

Yamada, T. (Toyobo Co, Shiga, Jpn); Imamura, Y. *Polym Eng Sci* v 28 n 6 Mar 1988 p 381-384.

**081419 MOGUCNOST USMERAVANJA TOPOHEMIJE REAKCIJE KALEM POLIMERIZACIJE PRETHODNOM NISKOTEMPERATURNOM PLAZMENOM AKTIVACIJOM POLIMERA.** [Possibilities for Controlling the Topochemical Reaction of Graft Polymerization by Low Temperature Plasma Pretreatment of the Polymer Matrix]. The possibilities of low-temperature plasma pretreatment (5 min 0.133 Pa) of PETP (polyester fiber) and its effects on topochemistry in acrylamide graft polymerization initiated by benzophenone have been studied. It was shown that the process of surface grafting of acrylamide is favoured by increased sorption ability and wetting of the fiber, due to its increased specific surface in the process of plasma pretreatment. Following the morphological changes of PETP after plasma pretreatment and/or in the grafting process (ESM method), a decrease of microporosity on the fiber surface was observed as a result of micropores filling with polyacrylamide. Surface grafting was proved by the IR method of the multiply disturbed entire internal reflection. (Author abstract) 26 refs. In Serbo-croatian.

## Adhesion

**081421 ADHESION OF POLY(ETHYLENE TEREPHTHALATE) FILM BY NOVOLAK TYPE EPOXY RESIN.** The adhesion of poly(ethylene terephthalate) (PET) is generally difficult without surface treatment. The peel strength of untreated biaxial stretching PET film laminate bonded with a novolak type epoxy resin was measured at 20°C, and the texture of the fracture surface after the peel test was observed with a scanning electron microscope. When the epoxy resin was fully cured, the PET film of thickness of 350  $\mu$ m broke, and, before breaking, the delaminating fracture of PET film surface occurred. The effects of testing temperature and rate on the peel strength were investigated. (Edited author abstract) In Japanese. 15 refs.

## Aging

**081422 STARZENIE PET.** [Aging of Polyethylene Terephthalate]. The theoretical aspects of PET ageing have been presented and the importance of free volume relaxation in this process accentuated. The results of studies on the effect of time, relative humidity and storage temperature as well as of relative viscosity of polymer on the changes in tensile yield and Dart impact of PET have been presented and discussed. It has been shown that free volume relaxation has a detrimental effect on the mechanical properties of bottles, films and preforms of amorphous PET. In general, it can be concluded that it is a poor practice to store PET articles in hot humid conditions. (Author abstract) In Polish.

**081424 SHELF LIFE EVALUATION OF AN ORIENTED POLYETHYLENE TEREPHTHALATE PACKAGE FOR USE WITH HOT-FILLED APPLE**

JUICE. A year-long storage study was undertaken to evaluate an oriented polyethylene terephthalate (OPET) container for use with hot-filled juice. Freshly-made juice as well as single-strength juice reconstituted from commercial apple juice concentrate were evaluated. The results indicated that the oxidation of the juice by way of oxygen permeation through the OPET barrier was slow enough to allow for a satisfactory shelf life as compared to glass-packaged samples over a 6-9 month period. Surface-to-volume effects did not become significant until late in the study. Difference and preference tests were used to establish shelflife comparison between OPET packages and glass-packaged products. (Edited author abstract) 9 refs.

## Chemical Reactions

**081425 AMINOLYSIS OF PET FIBERS WITH ETHYLENEDIAMINE VAPOR.** Aminolysis of poly(ethylene terephthalate) (PET) fibers with ethylenediamine (ED) of vapor phase was carried out at a temperature range from 60 to 120°C. Contents of primary amino group and bonded ED (nitrogen wt%) in the aminolyzed PET fibers were analyzed by the Ninhydrin method and an elemental analysis method. The content of amino group increased proportional to the vapor concentration of ED. Molar ratio of amino group to bonded ED was not virtually affected by the reaction temperature but by the vapor concentration of ED. (Author abstract) In Chinese. 3 refs.

**Crystallization** See Also SYNTHETIC FIBERS—Spinning.

**081426 CRYSTALLIZATION IN POLYMER MELT SPINNING.** The crystallization behavior of poly(ethylene) terephthalate (PET) melt spun into fiber monofilaments was examined using a laboratory set-up. The wind-up speeds ranged from free fall under gravity to 1500 m/min. The major additional variables that were manipulated included the mass flow rate and the filament temperature profile. The structure of the as-spun fibers was probed using tensile tests, differential scanning calorimetry, optical birefringence, and x-ray diffraction. It was found that while the filaments that had been spun nonisothermally were essentially amorphous, those that had been made under isothermal conditions at temperatures ranging from 180°C to 240°C were oriented and crystalline. In addition, the rate of oriented crystallization was much greater than that under quiescent conditions at the same temperature. (Edited author abstract) 21 refs.

**081430 CRYSTALLIZATION AND MULTI-MELTING BEHAVIOR OF POLY(ETHYLENE TEREPHTHALATE) MODIFIED BY SODIUM SALT OF 5-SULPHO-ISOPHTHALIC ACID.** The crystallization kinetics of the copolyester, poly(ethylene terephthalate) (PET) modified by sodium salt of 5-sulpho-isophthalic acid (SIPM), was investigated by means of differential scanning calorimeter. The experimental results and polar-microscopy observation all showed that the introduction of SIPM did not affect the nucleation of crystallization. Within the temperature range between their glass transition temperature  $T_g$  and melting point  $T_m$ , the crystallization rate of the copolyester sample decreased with increasing content of SIPM. The relative crystallization rate constant  $Z$  of SIPM/DMT (dimethyl terephthalate) 4 mol% sample was about 1% pure PET's  $Z$  value. For isothermal crystallized copolyester samples, DSC heating curves displayed multi-melting behavior. This was interpreted by molecular weight fractionation during crystallization and premelting-recrystallization mechanism. (Edited author abstract) 18 refs.

**081431 THERMOFORMING CRYSTALLIZING POLY(ETHYLENE TEREPHTHALATE) (CPET).** Nonisothermal crystallizing kinetics for nucleated polyethylene terephthalate (PET) are combined with transient heat transfer models to predict crystalline levels throughout the process of extruding and thermoforming crystallizing PET (CPET). The analysis compares distributed parameter finite difference analysis with a lumped parameter method. Material-environmental parametric studies are conducted using the lumped parameter method. The patent literature data are confirmed using an expanded version of the lumped parameter method. (Edited author abstract). 74 Refs.

**081432 EFFECTS OF INITIAL MORPHOLOGY AND MOLECULAR WEIGHT ON THE DEFORMABILITY OF POLY(ETHYLENE TEREPHTHALATE).** Solution-grown crystal (SGC) mats and solution-cast (SC) films of poly(ethylene terephthalate) (PET) were drawn by solid-state coextrusion followed by tensile drawing of the coextrudates. Drawabilities and properties

of the drawn films, such as mechanical and thermal properties, were investigated as functions of molecular weight, initial morphology, and drawing conditions. The initial morphology and molecular weight have a marked effect on the drawability and tensile properties of the resultant drawn films. The attainable maximum draw ratio increases with increasing molecular weight, and the highest draw ratio of 11.5 can be achieved by two-stage drawing of SC films prepared from pellets with an intrinsic viscosity of 1.43 dl/g. Such highly drawn films exhibit a tensile modulus of 17.5 GPa and strength at break of 400 MPa. At a given molecular weight, the drawability of SGC mats is lower than that for SC films; however, the efficiency of drawing is higher for the former than for the latter. (Edited author abstract) 23 refs.

**081433 ON STRUCTURAL FEATURES OF LARGE DEFORMATIONS OF ORIENTED AMORPHOUS POLYETHYLENE TEREPHTHALATE.** Structural features of the reorientation of oriented amorphous samples of PETP in the glassy state have been investigated. The methods used included wide angle X-ray diffraction, polarizing microscopy and the use of a coordinate datum point network. It is shown that during the initial drawing and subsequent stretching at various angles deformation of the samples is uniform in relation to the initial isotropic state. The relations obtained are described well within the framework of a model of a stable network of physical crosslinks with extension of the network in various directions under deformation. (Author abstract) 28 refs.

**Electric Conductivity** See Also PLASTICS FILMS—Electric Properties.

**081435 ELECTRICAL CONDUCTION IN POLYETHYLENE TEREPHTHALATE FILM.** The dc electrical conductivity ( $\sigma$ ) of polyethylene terephthalate (PET) has been investigated as a function of thickness (125 to 250  $\mu$ m) and applied fields at different temperatures ranging from 294 to 424 K with M-P-M sandwich configuration. The plots in  $\sigma$  versus  $1/T$  and current thermogram reveal that there are three regions of conduction separated by two transient zones of metallic nature. The regions I and II occurred in the glassy state having two temperature transitions recorded at 333 and 378 K. This has been explained on the basis of the cluster model. Activation energy ( $E_a$ ) of different conduction regions is correlated with the thickness of the sample and the applied field. These samples of the polymer also exhibit a hysteresis loop at and above 348 K indicating the polar nature of the sample. The low values of the activation energy ( $E_a \leq 1$ ) indicate predominance of electronic conduction. (Author abstract) 12 refs.

**081436 PRZEWODNICTWO ELEKTRYCZNE KRAJOWEJ FOLII Z POLI(TEREFTALANU ETYLENU).** [Electrical Conductivity of Domestic Poly-(Ethylene Terephthalate) Film.] The electric conductivity of samples of Estrofol PET film differing in the degree of orientation and crystallinity has been investigated. The current-voltage characteristics of the film in an electrostatic field of the intensity of up to  $6.5 \times 10^7$  V·m<sup>-1</sup> have been determined. An analysis of these characteristics reveals a high probability of an ionic mechanism of electrical conductivity of PET film. This conductivity only slightly depends on the molecular orientation and degree of crystallinity of PET. (Edited author abstract). 15 Refs. In Polish.

## Extrusion

**081437 PROPERTIES OF POLY(ETHYLENE TEREPHTHALATE) EXTRUDATE PREPARED BY HYPERBOLIC CONVERGENT FLOW AND HIGH PRESSURE.** The structure and properties of poly(ethylene terephthalate) segments prepared by high-pressure extrusion in a pseudohyperbolic die were examined. The translucent segments showed relatively high levels of orientation, crystallinity, and modulus. Higher melting point, larger crystal size, and higher loss modulus peak temperature ( $T_g$ ) were observed for these segments as compared with those prepared earlier in our laboratory using the conventional 90° conical die. This seems to indicate that a hyperbolic profile is very effective in producing and maintaining a highly aligned chain network in a flowing melt. (Author abstract) 11 refs.

**081439 NEW METHOD FOR QUICK DETERMINATION OF MOLECULAR ORIENTATION IN POLY(ETHYLENE TEREPHTHALATE) FILMS BY USE OF POLARIZED MICROWAVES.** A new polarized microwave method for determining the orientation of polymer molecules in films without contact and its application to poly(ethylene terephthalate) (PET) are presented. The angular dependence of transmitted microwave intensity allowed the orientation angle, the maximum to minimum intensity ratio, and the ratio of intensities in the transverse to the machine direction to be determined in as a short time as ca. 30s. With the results obtained from X-ray diffraction, mechanical breaking strength, infrared absorption, refractive index, and thermal shrinkage measurements, it was concluded that the orientation angle and the maximum to minimum ratio determined by the microwave method reflect, respectively, the direction and the degree of the orientation of PET chains. (Edited author abstract) 15 refs.

**081440 EFFECTS OF THERMAL TREATMENT ON BIAXIALLY ORIENTED POLY(ETHYLENE TEREPHTHALATE). II. THE ANISOTROPIC GLASS TEMPERATURE.** Thermal properties of an anisotropic biaxially oriented poly(ethylene terephthalate) (PET) were determined before and after further deformation of the Mylar film. Film shrinkage in different planar directions was monitored during and following initial heating. After stabilization for three days at 140°C, glass temperatures  $T_g$  were determined from the decrease in length of film strips and were found to vary in the different in-plane directions. An increase in anisotropy brought about by additional deformation in the direction of the greatest orientation enhanced the  $T_g$  difference from 8 to 16°C.  $T_g$  is highest in the direction of greatest orientation. (Author abstract) 8 refs.

Vallat, M.-F. (Univ of Pittsburgh, Pittsburgh, PA, USA); Plazek, D.J. *J Polym Sci Part B* v 26 n 3 Mar 1988 p 545-554.

**081441 EFFECTS OF THERMAL TREATMENT ON BIAXIALLY ORIENTED POLY(ETHYLENE TEREPHTHALATE). III. CREEP BEHAVIOR FOLLOWING VARIOUS THERMAL HISTORIES.** Elongational creep measurements were carried out on a biaxially oriented poly(ethylene terephthalate) (PET) film parallel to, orthogonal to, and at 45° to the principal optic axis. Measurements made after various thermal treatments which were intended to stabilize the physical state of the PET were shown to be ineffective. Samples were annealed at 140°C for 12 days and aged at 95°C for over 24 days before measurement without success. Thermal Cycling between 41 and 91°C which was also employed to stabilize the mechanical response also failed. Significant deceleration of the creep rate caused by densification of amorphous regions of the samples during storage below the glass temperature  $T_g$  is illustrated. Because of physical aging below  $T_g$  and morphological changes occurring above  $T_g$  during the various thermal treatments and histories, time-scale shift factors were found to be not unique. (Author abstract) 40 refs.

Vallat, M.-F. (Univ of Pittsburgh, Pittsburgh, PA, USA); Plazek, D.J.; Bhushan, B. *J Polym Sci Part B* v 26 n 3 Mar 1988 p 555-567.

**081442 PHOTOPHYSICAL STUDIES OF AMORPHOUS ORIENTATION IN POLY(ETHYLENE TEREPHTHALATE) FILMS.** The effects of uniaxial and biaxial extension on the intrinsic fluorescence of poly(ethylene terephthalate) (PET) films have been investigated. A power law relationship, valid for both uniaxially and biaxially deformed samples, was found between the fluorescence emission at 368 nm and the planar extension, which is defined as the product of the extension ratios in the transverse and machine directions. Dimethyl terephthalate (DMT) model compound studies indicate that the fluorescent species in the PET films is not the monomeric unit. A model incorporating energy migration in the non-crystalline region has been proposed to explain these results. (Edited author abstract) 28 refs.

**081444 OPTICAL INTERFERENCE METHOD FOR THE STUDY OF MOISTURE SWELLING IN PET FILMS.** A method for measuring moisture swelling

of amorphous PET films by using Rayleigh interferometer is reported. Plots of the optical path of light transmission in the polymer vs. soaking time were obtained, and from the same curves, the dependence of time on the moisture swelling, saturated water absorption and diffusion coefficient of PET films were estimated. These results are in agreement with those obtained by weighing method. It is shown that optical interference method is a simple but sensitive method for the study of water absorption and swelling in transparent polymer films. (Author abstract) 6 refs.

#### Flammability

**081445 FLAME-RETARDATION STUDIES OF POLY(ETHYLENE TEREPHTHALATE) FABRICS TREATED WITH tris DIBROMO ALKYL PHOSPHATES.** The flammability characteristics of tris(2,3-dibromopropyl) phosphate (TRIS-BP), a known carcinogen, has been compared with other tris dibromo alkyl phosphates which show reduced mutagenic responses in experimental studies. The effectiveness of these alternative chemicals in releasing hydrogen bromide (HBr), a recognized combustion inhibitor, has been measured and the results compared with flammability evaluation of polyester fabrics treated with these chemicals. Results indicate that tris(2,3-dibromo-3,3-dimethyl propyl) phosphate, while having reduced mutagenicity and nephrotoxicity in comparison to TRIS-BP, exhibits excellent flame-retardant characteristics when applied to polyester fabrics. Meanwhile, other chemicals studied show comparable flame retardation to TRIS-BP, but with substantial reduced mutagenicity. (Author abstract) 21 refs.

#### Forming

**081446 INVESTIGATION OF THE FORMATION OF POLY(ETHYLENE TEREPHTHALATE) WITH MODEL MOLECULES: KINETICS AND MECHANISM OF THE CATALYTIC ESTERIFICATION AND ALCOHOLYSIS REACTIONS. I. CARBOXYLIC ACID CATALYSIS (MONOFUNCTIONAL REACTANTS).** Monofunctional compounds (benzoic acid, heptyl alcohol, and 2-butoxy-ethanol) were used to investigate the kinetics of the esterification and the alcoholysis reactions. Carboxylic acids (benzoic acid) are the only catalysts present in the reaction medium. The factors which influence the kinetics of the esterification reaction were studied: the nature of the carboxylic acid (substituents on the benzene ring), the nature of the alcohol, the composition of the reaction medium (alcohol alone or with another solvent, ester, or water). The results point to an acyl type ( $A_{AC2}$ ) mechanism. (Edited author abstract) 7 refs.

#### Mechanical Properties

**081448 EFFECT OF STRETCHING CONDITIONS ON PROPERTIES OF AMORPHOUS POLYETHYLENE TEREPHTHALATE FILM.** The effect of stretching conditions on stress-induced crystallization of amorphous polyethylene terephthalate (PET) film has been studied. Cast PET film was stretched at 85°C with stretching rates ranging from 100% per minute to 600% per minute for various stretching ratios. The stretched film samples were annealed at 140°C both under tension as well as under relaxed conditions. Tensile properties were determined using Instron Tensile and results were compared. Tenacity, yield stress, and initial modulus were found to increase while elongation at break decreased with the increase in stretching rate. The degree of crystallinity was measured by x-ray diffraction as well as density methods. Birefringence and crystalline orientation factor values were determined experimentally and using these, amorphous orientation factor values were calculated. (Edited author abstract) 24 refs.

#### Medical Applications See Also PROSTHETICS—Blood Vessel Prostheses.

**081449 HYDROGELS FOR ARTIFICIAL TENDONS.** Natural tendon is a form of the connective tissues of the body which connects the muscle to the bone, so that the force produced in the muscle is transmitted to the bone. This function is mainly due to the bundles of fibers of collagen, a long-chain protein which imparts tensile strength and inextensibility to the tendon. The collagen fiber bundles, oriented in the longitudinal direction, have a rather complex structure which results in a waviness along their axis. The bundles are embedded in a gel of mucopolysaccharide acid, containing fibroblast cells which are the principal cellular components of tendon and are responsible for deposition of collagen. In this chapter, results of research on the use of fiber-reinforced hydrogels as tendon prostheses, jointly performed at the Institute of Macromolecular Chemistry (Prague, Czechoslovakia) and at the University of Naples, where further work is in progress, are reported and reviewed. 32 refs.

#### Molecular Structure

**081450 CRYSTAL MODULUS AND STRUCTURE OF ORIENTED POLY(ETHYLENE TEREPHTHALATE).** Crystal modulus measurements have been made on a number of samples of drawn poly(ethylene terephthalate) tape. The apparent crystal modulus was found to vary systematically with the degree of tilt of the crystalline c axis from the fiber axis. Using this fact, a value of 110±10 GPa was deduced for the intrinsic crystal modulus in the chain direction. It is considered that this value is more realistic than previously reported values since specimen morphology has been taken into account carefully in a systematic fashion. (Author abstract) 26 refs.

**081452 PROCESSING-STRUCTURE-PROPERTY RELATIONSHIPS IN POLY(ETHYLENE TEREPHTHALATE) BLOWN FILM.** An investigation was undertaken to establish processing-structure-property relationships in poly(ethylene terephthalate) (PET) blown film. For the study, a commercial grade of PET was used to fabricate the film specimens by means of a tubular film blowing process. In this process, the stretch temperature was accurately controlled by an oven. The structure of the blown film samples was characterized by density, bulk birefringence, flat plate wide-angle X-ray scattering, and pole figure analysis. The processing variables, namely, takeup ratio, blowup ratio, and stretch temperature were found to significantly affect the bulk birefringence and density of the oriented PET blown film samples. It was found that both the bulk birefringence and density of the specimens increased upon annealing at an elevated temperature. Both the crystalline and amorphous orientation functions were calculated from the data of bulk birefringence, density, and the pole figure analysis. (Edited author abstract) 49 refs.

**Sheet**

**081453 POLARIZED REFLECTION SPECTRUM AND MOLECULAR ORIENTATION IN UNIAXIAL DRAWN POLY(ETHYLENE TEREPHTHALATE).** The polarized electronic spectrum of oriented poly(ethylene terephthalate) (PET) sheets was obtained from the specular reflection spectrum using the Kramers-Kronig relationship. The surface orientation function of drawn and drawn/annealed PET sheets was determined. The bulk orientation functions in the crystalline and amorphous regions were evaluated from wide-angle X-ray diffraction and sonic modulus measurements. On annealing of drawn PET sheets, the crystalline orientation and crystallinity were much improved, but the amorphous orientation function showed a minor decrease. The overall molecular orientation in the surface of the drawn PET sheet was shown to be approximately equivalent to the molecular orientation in the bulk. (Edited author abstract). 35 Refs.

**Shrinkage** See POLYCARBONATES—Stability.

**Sorption**

**081454 SORPTION BEHAVIOR OF POLY(ETHYLENE TEREPHTHALATE) FOR n-CARBOXYLIC ACID.** Sorption behavior of poly(ethylene terephthalate) (PET) was studied over a wide temperature range by using the method of Gas Chromatography. PET was used as a stationary phase in the column; mobile phases (probes) were a series of carboxylic acids with carbon numbers of 2, 3, 4, and 5: acetic acid, propionic acid, butyric acid and valeric acid. Results of previous work, in which the probes were a series of linear alcohols, i.e., ethanol, n-propanol, n-butanol, n-pentanol and o-chlorophenol, were compared. The sorption isotherms were determined from the peak profile. For carboxylic acid, the amount of the probe adsorbed decreased with temperature and with increasing chain length of the probe. The sorption behavior of three systems were analysed using the adsorption isotherms, B.E.T. plot, and Flory-Huggins parameters. (Edited author abstract) 10 refs. In Japanese.

**Structure**

**081458 EFFECT OF ANNEALING AND DRAWING ON THERMOLUMINESCENCE OF POLY(ETHYLENE TEREPHTHALATE).** As a fundamental study on the structure and properties of poly(ethylene terephthalate) (PET), thermoluminescence (TL) of X-ray irradiated PET films at both low temperatures (starting from liquid-nitrogen temperature) and high temperatures (starting from room temperature) was investigated by means of the glow curve and thermal decay. It is concluded that most of the electron traps in X-ray irradiated PET films are located in the amorphous region in both low- and high-temperature TL. It is especially emphasized that crystal interfaces also contribute to the high-temperature TL of annealed samples and that the relaxed state of amorphous chains is more favorable to TL than the tensioned state. (Author abstract) 16 refs.

**Thermal Effects** See Also POLYMERS—Mechanical Properties.

**081460 THERMAL ANALYSIS OF HEAT SET POLY(ETHYLENE TEREPHTHALATE) AND THE HEAT SETTING TEMPERATURE.** In our examination of the differential scanning calorimetry (DSC) curve of annealed or heat set polyester samples from textile mills, we have observed three kinds of thermograms. The first type of curve shows an endotherm prior to melting and the second type exhibits an exothermic curve. The third type of curve is a combination of the first two. We thought that the exo-shifts in these curves might be caused by some oligomers present in the fiber. We used two separate methods to remove the oligomers: extraction of the polyester with a mixture of methanol and chloroform, and heating the material to a high temperature. The experiments show that the exo-shift in the DSC curve might be due to oligomers present in the commercial fabric, which are washed out on extraction with a solvent mixture or polymerized when heated beyond the melting point of polyester. 5 Refs.

## Thermodynamic Properties

**081462 TSC STUDIES ON SUB-T<sub>g</sub> STORAGE OF POLYETHYLENE TEREPHTHALATE.** The Thermally Stimulated Current (TSC) spectra of a series of Sub-T<sub>g</sub> annealed polyethylene terephthalate (PET) specimens have been measured. It is found that there is only one peak at 80°C above room temperature, which related to the thermo-relaxation of frozen-in dipoles. The activation energy of such dipole motion has been calculated. The relation between the maximum current and the storage time can be explained by the free volume theory and agrees with the results from the excess thermodynamic properties. Compared with differential scanning calorimeter (DSC) and tensile stress-strain method, TSC is a simpler and more sensitive method in studying Sub-T<sub>g</sub> annealed polymers. (Author abstract) 14 refs.

## Thick Films

**081463 LONGITUDINAL MAGNETORESISTANCE IN POLYETHYLENE TEREPHTHALATE FILM.** The longitudinal magnetoresistance ( $\Delta\rho/\rho_0$ ) of polyethylene terephthalate (PET) film of thickness 125  $\mu\text{m}$  has been measured both in glassy and rubbery state in electric field up to  $80 \times 10^5$  V/m and in magnetic field up to 0.27 kG. The sample showed negative magnetoresistance at 393 K at a low electric field. The explanation of negative magnetoresistance is made in terms of scattering by localized spins. The electric field produces an opposite effect in glassy and rubbery state of the polymer, i.e. the magnetoresistance decreases with electric field at and below 378 K, on the other hand  $\Delta\rho/\rho_0$  increases with electric field above 378 K. The energy gap at zero magnetic field is widened and shortened with electric field, in glassy and rubbery state respectively, which affects the carrier mobility and hence the magnetoresistance. (Author abstract) 11 refs.

**081464 EFFECTS OF PREIRRADIATION DOSE AND GRAFTING ON THE ANTITHROMBOGENICITY OF POLYETHYLENE RADIATION-GRAFT COPOLYMERIZED WITH ACRYLAMIDE.** To clarify the optimal preparative conditions for the polyethylene (PE) radiation-graft copolymerized with acrylamide (AAM) in terms of the surface antithrombogenicity, the effects of preirradiation dose in air and grafting percentage on the antithrombogenicity were evaluated by implantation of the tubes (3 mm i.d.) into canine peripheral veins. The lowest contact angle of water, 23°, was found at 28% grafting regardless of the dose. The overall antithrombogenicity increased in the order of  $1.8 < 5.6 < 3.6 < 7.2$  MR and showed a peak at about 25% grafting, where contact angle was 26°, independent of dose. The ratios of  $N_{1s}/C_{1s}$  obtained from ESCA data at a photoelectron takeoff angle of 15° corresponded well to

the trend of their antithrombogenicities. The surface roughness varying with both dose and grafting percentage was considered to enhance the peaks appeared in their ratios. (Edited author abstract) 12 refs. In Japanese.

**081466 NEW STAINING TECHNIQUE OF RuO<sub>4</sub> SOLUTION IN ORGANIC SOLVENTS FOR RESOLVING THE LAMELLA STRUCTURE IN POLYMERS.** A solution of ruthenium tetroxide (RuO<sub>4</sub>) in carbon tetrachloride has been used as a staining medium for resolving the lamella structure in both polyethylene and polypropylene with the transmission electron microscope. Staining in the organic medium is more efficient than in the vapor phase of an aqueous solution of RuO<sub>4</sub> and more convenient than in the vapor of solid crystalline RuO<sub>4</sub> for both polymers. The organic solution of RuO<sub>4</sub> seems to be a universal staining medium for revealing the fine morphology in hydrophobic polymers. (Author abstract) 6 refs.

**081467 COMPARISON OF OLIGO(ETHYLENE OXIDE)-SUBSTITUTED POLYSILOXANES WITH POLY(ETHYLENE GLYCOL) AS STATIONARY PHASES FOR CAPILLARY CHROMATOGRAPHY.** The gas-chromatographic properties of a new oligo(ethylene oxide)-substituted (glyme) polysiloxane stationary phase and an 18-crown-6-substituted (crown) polysiloxane phase were compared to Carbowax 20M and a bonded poly(ethylene glycol) (Bondable PEG). The glyme polysiloxane was found to have an operational temperature range of 20-280°C and a selectivity similar to that of Carbowax 20M. The crown polysiloxane was found to have unique selectivity, partly because of the size and shape of the crown ether cavity and the structures of solute molecules. Selected applications including the analysis of alcohols, fusel oils, and nitrogen heterocycles are demonstrated. (Author abstract) 15 refs.

**081469 POLY(ETHYLENE OXIDE) AND RELATED HYDROGELS.** Poly(ethylene glycols) (PEG) and poly(ethylene oxides) (PEO) are terms for materials containing a multiplicity of connected units of the structure -CH<sub>2</sub>CH<sub>2</sub>O-. PEGs are a subset of PEOs being those which contain a hydroxyl group on each end of their chain

HO(CH<sub>2</sub>CH<sub>2</sub>O)<sub>n</sub>H. They are a fascinating group of nonionic water soluble materials which appear simple but are quite complex in their solubility behavior and interaction with solvents and other polymer molecules. Their industrial significance enhances the value of any understanding which fundamental research can reveal of their molecular structure in the solid state or in association with solvents or solutes. This chapter provides a selective and necessarily brief overview of PEO hydrogels with special reference to their application in drug delivery. 76 refs.

## Adhesion

**081470 HOT-MELT ADHESION AND WETTABILITY OF POLYETHYLENE/METAL IN THE VICINITY OF THE METAL MELTING POINT.** The effect of polyethylene temperature on the bonding strength and the wettability between polyethylene and a metal was investigated. The results were compared with the already reported results for polymer/polymer systems. It was clarified that the bonding strength showed a peak when bonding was performed at a temperature near the melting point of the metal and that the wettability of the metal surface by the molten polyethylene drop reached a minimum at this temperature. It was previously confirmed that the same tendency also occurred for the polymer adherend. In other words, it is proved that the interaction between polymer and polymer and between polymer and metal undergoes similar changes near the melting point of the adherend of each system, though polymer and metal have different structures. A Sn-Pb alloy and a Sn-Bi alloy were used in the experiment. 5 refs.

## Adsorption

**081471 ORGANIZATION OF THE LAYERS OF POLYETHYLENE OXIDE GRAFTED WITH DIFFERENT DENSITIES ON SILICA.** EPR spectroscopy of labeled grafted polyethylene oxide chains has been used to estimate the ratio of the population of free end segments in solution to that of adsorbed segments on a silica surface as a function of temperature. The configurations of the chains have been studied in the case of certain extreme coverages. Grafted molecules of mol wt 2000 with grafting ratios of 0.045, 0.057, 0.126, and 0.42 molecules/nm<sup>2</sup> were in contact with benzene. DSC thermograms are also shown. At low grafting ratios the chains lie very flat, whereas at higher grafting ratios the layer is more organized. (Author abstract) 22 refs.

## Aging

**081472 AGING OF POLYETHYLENE FOR CABLE INSULATION.** Electrical and spectrographic measurements were made of various characteristics of polyethylene aged using various aging methods. The results show correlation between aging time and electrical parameter degradation, and a correlation between aging time and the infrared absorption spectra. This performance implies relationships between measurable changes in infrared absorption spectra and electrical degradation due to aging. Specifically, the data obtained for both polyethylene sheet and foil samples imply the following: that (1) aging caused by multifactor stresses causes a degradation of electrical properties such as dielectric loss factor and breakdown strength; and (2) the degradation in electrical properties is associated with an increase in infrared absorption in the 1720-cm<sup>-1</sup> band. 6 refs.

**081476 NEW HORIZONS IN ADVANCED ORIENTED FIBER.** Achievement of exceptional properties in films/fibers generally requires very high to ultra high molecular weights and very high degrees of orientation. A brief description of the fiber related technologies used to maximize orientation in high performance fibers, e.g., solid state extrusion, special drawing methods, gel spinning, and liquid crystal spinning are reviewed. A detailed comparison of the fiber properties resulting from these technologies is also shown. Particular emphasis is placed on describing the upgrading of polyethylene to a high performance fiber product through several of these technologies. Gel/solution spinning of ultra high molecular weight polyethylene (UHMWPE) is especially highlighted. The latest worldwide efforts to commercialize gel spun fibers are discussed as well as the applicability of the process to other thermoplastics. Applications illustrating the use of high performance fibers in various end use areas are summarized. The primary properties critical to each are also outlined. (Author abstract). 5 Refs.

**Biodegradation**

**081477 BIODEGRADATION OF POLYETHYLENE AND THE INFLUENCE OF SURFACTANTS.** Low density polyethylene (LDPE) samples were exposed to UV irradiation for 27 days. Thereafter they were added to an abiotic and a biotic environment. By increasing the amount of polyethylene added to a soil system it was possible to compare how different amounts of irradiated PE affect the degradation rate and the evolution of  $\text{CO}_2$ . The degradation rate seems to be independent of the amount of PE added to the soil system but dependent on the biotic activity. The amount of  $\text{CO}_2$  evolved follows close to a linear relationship. The addition of a surfactant to a nutrient solution containing PE results in an increased degradation rate. In contrast to the behaviour of similar samples without surfactant, this sample sinks to the bottom of the flask instead of floating on the surface of the solution. (Author abstract). 16 Refs.

**081478 POLYOLEFIN BLENDS: 1. EFFECT OF EPR COMPOSITION ON STRUCTURE, MORPHOLOGY AND MECHANICAL PROPERTIES OF HDPE/EPR ALLOYS.** Differential scanning calorimetry, wide-angle X-ray diffraction, morphology, and mechanical and impact properties of a high-density polyethylene (HDPE)/ethylene-propylene copolymer (EPR) blend (80/20 weight ratio), with the EPR copolymer having various compositions, have been investigated. The results show no evidence of cocrystallization between HDPE and the EPR copolymers even at the highest  $\text{C}_2$  content. During blend mixing, the copolymers are able to dissolve HDPE low-molecular-weight chains, giving rise to a system with lower crystallinity and higher HDPE crystallite perfection. The observed behavior is very similar to that of an isotactic polypropylene/ethylene-propylene copolymer studied. (Edited author abstract) 13 refs.

Greco, R. (CNR, Naples, Italy); Mancarella, C.; Martuscelli, E.; Ragosta, G.; Yin, Jinghua. *Polymer* v 28 n 11 Oct 1987 p 1922-1928.

**081479 PRODUCTION OF BLOWN FILM FROM LDPE WITH ADDITIONS OF LLDPE.** Currently the major field of applications of LLDPE is the film sector, with film for heavy-duty sacks as well as stretch and shrink film ranging on top. The substitution of LLDPE or LDPE/LLDPE blends for LDPE leads to an improved profile of film properties and to reduced costs of film production while retaining the required quality. The study under discussion uses an LDPE type and an LLDPE type as well as blends to demonstrate the influence of the mixing ratio of these two polyethylenes on the thermal and rheological behavior of the materials, their processing properties and the property profile of blown film. 20 refs.

Schuele, H.; Wolff, R. *Kunstst Ger Plast* v 77 n 8 Aug 1987 p 6-8.

**081480 LLDPE/LDPE BLENDS FOR EXTRUSION COATING.** The first part of this paper deals with the extrusion coating processability of low linear density polyethylene (LLDPE) LDPE blends. Various LLDPEs and LDPEs mixed in different ratios were tested for processability on Exxon Chemical's pilot extrusion coating line. This testing resulted in a set of useful correlations between the blend composition and its processability. The second part covers the end-use performance of extrusion coatings with selected LLDPE/LDPE blends. Typical

coatings onto paper as well as onto aluminum were tested for some expected property improvements. The results give a positive outlook for the use of LLDPE blended with LDPE in extrusion coating. (Edited author abstract)

**081481 MISCIBILITY OF CHLORINATED POLYMERS WITH EPOXIDIZED NATURAL RUBBER: 3. BLENDS WITH CHLORINATED POLYETHYLENES.** The miscibility of epoxidized natural rubber (ENR) at two levels of epoxidation (25 and 50 mol%) with chlorinated polyethylene containing 25 and 48 wt% chlorine was investigated over the complete composition range. The techniques used were dynamic mechanical analysis, differential scanning calorimetry, phase-contrast microscopy and stress-strain properties. Miscibility can be traced to specific interactions involving the chlorine atom and the oxirane group, in analogy to low-molecular-weight compounds. The results are in line with previous work on the miscibility of ENR with other chlorinated polymers. All the above ENR/chlorinated polymer compatibility data were used to test a compatibility prediction scheme based on the copolymer-copolymer miscibility theory. (Author abstract) 41 refs.

Margaritis, Antonis G. (Univ of Patras, Patras, Greece); Kallitsis, John K.; Kalfoglou, Nikos K. *Polymer* v 28 n 12 Nov 1987 p 2122-2129.

**081482 MODIFIED BLEND CHAMBER SOLVES CRITICAL START-UP PROBLEMS.** In 1984, shortly after startup of E.I. du Pont de Nemours & Company's high density polyethylene (HDPE) plant in Matagorda, Tex., plant personnel discovered that the pellet blenders were not performing as expected. As a result, DuPont conducted an extensive test of the blenders' performance and collaborated with the blenders' supplier to develop a modification of the blend chamber. Unmodified blenders produced product whose ratio of fill to unload variance was 2.2, which is unacceptable blending. After modification, the ratio was 68.7, which constitutes outstanding blending.

Anon. *Powder Bulk Eng* v 1 n 12 Dec 1987 p 22-25.

**081483 CROSS-LINKING EFFECT OF POLYETHYLENE-POLYPROPYLENE BLEND FILMS PREPARED BY GELATION/CRYSTALLIZATION FROM SOLUTION.** Cross-linking of polyethylene-polypropylene blend films, prepared by gelation/crystallization from solutions, was done according to the following two methods. One was carried out under elongation of the blend gel films containing dicumyl-peroxide. The other was with electron-beam irradiation of the undrawn specimens and subsequently the specimens were elongated. The mechanical properties of the resultant specimens in undrawn and drawn states were found to become much weaker with increasing polypropylene content. (Edited author abstract) 25 refs.

Sawatari, Chie (Nara Women's Univ, Nara, Jpn); Matsuo, Masaru. *Polym J* v 19 n 12 1987 p 1365-1376.

**081484 ELONGATIONAL BEHAVIOR OF LOW DENSITY/LINEAR LOW DENSITY POLYETHYLENES.** Rheological data have been collected in isothermal elongational flow for three different types of blends, made from one low density polyethylene and three linear low density samples. In addition to the transient curves, elongation at break data are also reported. The influence of the composition and of the molecular weight of the linear low density polyethylene is discussed. (Author abstract) 22 refs.

La Mantia, F.P. (Univ of Palermo, Palermo, Italy); Valenza, A.; Acierno, D. *Polym Eng Sci* v 28 n 2 Jan 1988 p 90-95.

**081485 MICROSTRUCTURAL CHANGES IN POLYETHYLENE-POLYPROPYLENE BLENDS AS REVEALED BY MICROHARDNESS.** Microhardness is used to examine the microstructural changes of a series of polyethylene (PE)/polypropylene (PP) blends in a wide composition range. This study complements previous hardness results obtained on high-density/low-density polyethylene systems. The use of isotactic polypropylene, as a blend component allows investigation of a material in which the hardness of the amorphous phase, contrary to PE, differs from zero. The influence of treatments such as crystallization of the PP-phase in the presence of molten PE, within the blend, or annealing the PE phase, while leaving the PP component unmodified, are discussed. (Edited author abstract) 17 refs.

Salazar, J. Martinez (CSIC, Madrid, Spain); Tijero, J.M. Garcia; Calleja, F.J. Balta. *J Mater Sci* v 23 n 3 Mar 1988 p 862-866.

**081486 CRYSTALLIZATION KINETICS OF LDPE/Ny6 BLENDS.** The crystallization behaviour of low density polyethylene/nylon 6 blends has been investigated as a function of the composition. The melting points of the polymers are almost uninfluenced by the presence of the other homopolymers except for blends with a nylon content of 75-90%. Blends with 10% nylon content do not exhibit the crystallization peak during the cooling step probably because of the low concentration and high viscosity of the low density polyethylene matrix. The crystallinity degree of the polyethylene is independent of the composition, while some variations are shown by the polyamide. Finally the rate of nucleation is strongly affected by the composition, in particular for the nylon phase. (Author abstract). 11 Refs.

La Mantia, F.P. (Univ di Palermo, Palermo, Italy); Valenza, A. *J Therm Anal* v 34 n 2 Mar-Apr 1988 p 497-502.

## Blow Molding

**081487 LARGE-PARTS BLOW MOLDING TAKES ON A NEW MEASURE OF COST-EFFICIENCY.** Tighter resin tailoring (involving performance-enhancing engineering grades as well as polyethylene) teams up with problem-solving advances in equipment (involving faster cycling and greater automation) to galvanize growth in traditional markets and open up a broad variety of new opportunities. (Author abstract)

Smoluk, George R. *Mod Plast* v 64 n 10 Oct 1987 p 61-64.

## Bonding

**081488 HOT-MELT ADHESION AND WETTABILITY BETWEEN POLYETHYLENE AND OTHER POLYMERS IN THE VICINITY OF THE ADHEREND MELTING POINT.** The effect of bonding temperature on the bonding strength of polyethylene to polypropylene or other polymers was investigated. It became clear that the interfacial bonding strength reached maximum strength at a bonding temperature in the vicinity of the melting point of the adherend (i.e., the polymer having the higher melting point). The effect of temperature on the contact angle of the molten polymer having the lower melting point on the adherend surface was also investigated. The wettability of the adherend by the molten polymer drop was considerably reduced at the temperature near the melting point of the adherend. The relationship between increasing adhesiveness and decreasing wettability was found out. (Author abstract) 9 refs.

## Chlorination

**081489 CHLORINATED HIGH DENSITY POLYETHYLENE. I. CHAIN CHARACTERIZATION.** High density polyethylene has been chlorinated by three different methods: in suspension and in solutions of two different solvents. Carbon-13 NMR and infrared analysis show that chlorination in chlorobenzene solution leads to statistically random distribution while chlorination in suspension gives highly blocky substitution. An intermediate distribution was obtained by chlorination in tetrachloroethane solution. (Author abstract). 6 Refs.

Chang, B.H. (Case Western Reserve Univ, Cleveland, OH, USA); Zeigler, R.; Hiltner, A. *Polym Eng Sci* v 28 n 18 Sep 1988 p 1167-1172.

**081490 CHLORINATED HIGH DENSITY POLYETHYLENE. II. SOLID STATE STRUCTURE.** Chlorination of high density polyethylene results in polymers which consist of unmodified methylene units and chlorinated methylene co-units. The effect of the concentration and distribution of chlorinated units on the solid state structure has been examined by thermal, wide angle X-ray diffraction and dynamic mechanical analysis. As the substitution becomes more random, the crystallinity, crystallite size, and crystalline perfection decrease for a given chlorine content. The chlorinated units are shown to be capable of co-crystallizing, and the concentration of chlorine in the crystalline phase increases as the distribution is made more random. (Edited author abstract). 31 Refs.

## Chromatographic Analysis

**081491 CHROMATOGRAPHIC-MASS-SPECTROMETRIC STUDY OF THE COMPOSITION OF COMMERCIAL POLYETHYLENEPOLYAMINES.** The authors report the results of a study, with the aid of gas chromatography in conjunction with mass spectrometry (GC-MS), of the compositions of distilled polyethylenepolyamines (PEPA). Experimental results indicate that the main components of distilled polyethylenepolyamines and PEPA type B produced in the USSR are the corresponding linear oligomers. Technical polyethylenepolyamines types A, C, and D are mixtures mainly of compounds containing piperazine and dipiperazine. 9 refs.

Bobylev, V.A.; Dalin, A.R.; Utsal', V.A. *J Appl Chem USSR* v 59 n 7 pt 2 Jul 1986 p 1452-1455.

**081492 ADSORPTION-EXCLUSION BEHAVIOUR OF POLYETHYLENE GLYCOL MACROMOLECULES DURING CHROMATOGRAPHY.** The authors have investigated the chromatography of polyethylene glycols on crosslinked copolymer Solose K sorbents with varied hydrophobic-hydrophilic properties. The experimental data as a whole are described by the theoretical dependences of the distribution coefficient on M. It is proposed that the chromatographic regime be characterized by the parameter of adsorption interaction  $\tau$ , a measure of the deviation of the system from critical conditions. The critical conditions are found delineating the regimes of exclusion and adsorption chromatography. It is shown that the transition from exclusion to adsorption comes about with increase in the content in the sorbent of the hydrophobic components and for sorbents with fixed composition with fall in pH or with rise in temperature. (Edited author abstract) 18 refs.
